MONTICELLO NUCLEAR GENERATING PLANT
Docket No. 50-263 License No. DPR-22

Submittal of the Core Operating Limits Report for Cycle 20

The Core Operating Limits Report (COLR) for Cycle 20, Rev 0, is enclosed. This report provides the values of the limits for Cycle 20 as required by Technical Specification Section 6.7.A.7. These values have been established using NRC approved methodology such that all applicable limits of the plant safety analysis are met.

It is noted that this COLR incorporates changes given in a September 22, 1999 notification letter from General Electric (Reference 1) with regard to the Safety Limit Minimum Critical Power Ratio (SLMCPR), and as communicated to the NRC in our SLMCPR License Amendment Request of December 16, 1999 (Reference 2).

The COLR reflects a SLMCPR of 1.11 for two-loop operation, and 1.12 for single-loop operation for all fuel in Cycle 20.

The appropriate OLMCPR values in our core monitoring system will be changed prior to plant startup.

Please contact Sam Shirey at 612-295-1449 if you have any questions related to this submittal.

MONTICELLO NUCLEAR GENERATING PLANT

Core Operating Limits Report

Cycle 20

Revision 0

Prepared By:	David J. Pribyl Lead Engineer, Nuclear Analysis and Design	1/27/00 Date
Reviewed By:	D. G. Wegener Superintendent, Nuclear Engineering - Monticello.	1-28-0 Date
Reviewed By:	R. J. Rohrer Project Manager, Nuclear Analysis and Design	1/27/00 Date

Introduction

This report provides the values of the limits for Cycle 20 as required by Technical Specification Section 6.7.A.7. These values have been established using NRC approved methodology and are established such that all applicable limits of the plant safety analysis are met.

A SLCPR of 1.11 was used for two-loop operation for all fuel types in Cycle 20 (GE10, GE11, and GE12). The SLCPR for single-loop operation is 1.12. These values are consistent with the values specified by GE in Reference 2.

This report includes stability exclusion region definition, buffer region definition, and power distribution limits as required by amendment 97 to Monticello's operating license approved by the NRC in Reference 4.

Rod Block Monitor Operability Requirements

The MCPR limit associated with the Rod Block Monitor operability is:

MCPR < 1.68

Whenever the monitored core MCPR is less than 1.68, a limiting control rod pattern exists and the RBM system is required to be operable.

Reference Technical Specification Section 3.2.C.2.a

Rod Block Monitor Upscale Trip Setpoints

Low Trip Setpoint (LTSP)	$\leq$	120/125 of full scale
Intermediate Trip Setpoint (ITSP)	$\leq$	115/125 of full scale
High Trip Setpoint (HTSP)	$\leq$	110/125 of full scale

Reference Technical Specification Sections: Table 3.2.3 Item 4.a, Table 3.2.3 Note 8.

Minimum Critical Power Ratio

The Minimum Critical Power Ratio (MCPR) limit shall be determined for two Recirculation Loop Operation as follows:

If thermal power > 45%, then the MCPR for GE10 is the greater of:

$1.51 * K_P$ (K_P from Figure 3) or $TICPR_F$ from Figure 5.

If thermal power > 45%, then the MCPR for GE11 fuel is the greater of:

$1.49 * K_P$ (K_P from Figure 4) or $TICPR_F$ from Figure 5.

If thermal power > 45%, then the MCPR for GE12 Fuel is the greater of:

$1.51 * K_P$ (K_P from Figure 4) or $TICPR_F$ from Figure 5.

If thermal power $\leq$ 45%, then the MCPR limit for GE10 is obtained in Figure 3.
If thermal power $\leq$ 45%, then the MCPR limit for GE11 and GE12 fuel is obtained in Figure 4.

For single recirculation loop operation the MCPR limit as defined previously by two recirculation loop operation is increased by the following adders:

0.01 ΔMCPR to account for core flow measuring and TIP reading uncertainties.

Reference Technical Specification Section: 3.11.C.

When both recirculation loops are in operation, the MCPRs calculated above may be replaced by values calculated in Table 3 if taking credit for scram speeds.

Power-Flow Operating Map

The Power-Flow Operating Map based on analysis to support Cycle 20 is shown in Figures 6 & 7. This Power-Flow Operating Map is consistent with the rated power of 1775 as described in References 3, 5, and 6.

Maximum Average Linear Heat Generation Rate as a Function of Exposure

When hand calculations are required, the Maximum Average Linear Heat Generation Rate (MAPLHGR) for each fuel bundle design as a function of average planar exposure shall not exceed the limiting lattice (excluding natural Uranium) provided in Table 1 (based on straight line interpolation between data points) multiplied by the smaller of the two MAPFAC factors determined from Figures 1 and 2.

The MAPLHGR limits in Table 1 are conservative values bounding all fuel lattice types (excluding natural Uranium) in a given fuel bundle design and are intended only for use in hand calculations as described in Technical Specification 3.11.A. No channel bow effects are included in the bounding MAPLHGR values below because there are no reused channels. MAPLHGR limits for each individual fuel lattice design in a bundle design as a function of axial location and average planar exposure are determined based on the approved methodology referenced in Monticello Technical Specification 6.7.A.7.b and loaded in the process computer for use in core monitoring calculations.

Reference Technical Specification Section 3.11.A.

Core Stability Requirements

Stability Exclusion Region
The stability exclusion region is shown in Figure 6 and is given in greater detail in Figure 7.

Stability Buffer Region
The stability buffer region is shown in Figure 6 and is given in greater detail in Figure 7.

Power Distribution Controls
Prior to intentionally entering the stability buffer region, the hot channel and core wide decay ratios will be shown to be within the stable portion of Figure 8. While operating in the stability buffer region, the hot channel and core wide decay ratios will be maintained within the stable portion of Figure 8.

Reference Technical Specification Section 3.5.F.

Scram Time Dependence

Technical Specification 3.3.C provides the scram insertion time versus position requirements for continued operations. Technical Specification 4.3.C provides the surveillance requirements for the CRDs. Data from testing of the CRDs, or from an unplanned scram, is summarized in Surveillance Test 0081. Using this cycle specific information, values of τ_{20} can be calculated in accordance with the equation at the 20% insertion position, which is:

$$\tau_{20} = \frac{\sum\limits_{i=1}^{n} N_i t_i}{\sum\limits_{i=1}^{n} N_i} + 0.0875 \left[\frac{N_1}{\sum\limits_{i=1}^{n} N_i} \right]^{\frac{1}{2}}$$

where:
τ_{20} = the weighted cycle average scram time at a 95% confidence level at the 20% insertion position.

n = the number of surveillance tests performed following core alterations.

N_i = the number of control rods measured in the ith test.

N_1 = the total number of active rods measured in the first test following core alterations.

t_i = average scram time at the 20% insertion position of all rods measured in the ith test.

τ_{20} = 0.900 seconds shall be assumed until cycle specific scram data following a core alteration becomes available. When scram insertion time data is available, credit may be taken for faster insertion times, if desired. It should also be noted that when data does become available, the average scram time values must be calculated with either CRD insertion time data at reactor pressures above 965 psia, or with data that is corrected for low reactor pressures in accordance with Surveillance Test 0081 Appendix A.

After obtaining the cycle specific values of τ_{20} for the 20% insertion positions, a comparison can be made to Table 3 in order to get the scram time adjusted OLCPR. The value of the scram time adjusted OLCPR is obtained from Table 3 by linearly interpolating the value of τ at the 20% insertion position. Note that extrapolation is not permitted in Table 3.

The adjustment to the OLCPR limit can only be performed if the plant is operating with both recirculation loops. Credit for scram insertion times may not be taken if the plant is operating with a single recirculation loop.

TABLE 3
Full Power/Flow OLCPR as a Function of Scram Time

τ_{20}	0.773	0.900
OLCPR GE10	1.45	1.51
OLCPR GE11	1.45	1.49
OLCPR GE12	1.45	1.51

NOTES
1. Credit for scram insertion times may not be taken if the plant is operating with a single recirculation loop.

Sample Interpolation

After a Surveillance Test 0081 has been completed for Cycle 20 the results can be used to calculate a new average scram insertion time at the 20% insertion position. This time can then be linearly interpolated to change the OLCPR values found in Table 3. If the scram insertion time changed from 0.900 seconds to 0.800 seconds then the OLCPR values would change as follows:

Table 4
Sample Interpolation for Full Power/Flow OLCPR as a Function of Scram Time

τ_{20}	0.773	0.800	0.900
OLCPR GE10	1.45	1.47	1.51
OLCPR GE11	1.45	1.46	1.49
OLCPR GE12	1.45	1.47	1.51

For example, from Table 4 the OLCPR for GE10 would be 1.47 instead of 1.51 at the technical specification scram insertion time thus increasing operating margin.
