

## 2.3.3 Water Quality

This section considers the water quality of surface-water bodies and groundwater aquifers that could (1) affect plant water use and effluent discharge, or (2) be affected by the construction or operation of STP 3 & 4. This discussion is based on the surface water and groundwater data associated with the construction and operation of STP 1 & 2. No surface or groundwater quality data would preclude the development of STP 3 & 4. As discussed in Subsection 2.3.2, a review of the STP site's surface water rights and groundwater use indicates that sufficient water is available for construction and operation of STP 3 & 4.

### 2.3.3.1 Surface Water

STP 3 & 4 will use a closed-cycle circulating water system similar to that used for STP 1 & 2 (see Section 3.4). The existing 7000-acre Main Cooling Reservoir (MCR) will be used for dissipation of waste heat. Makeup water for the MCR will be diverted from the Colorado River and provided by means of the Reservoir Makeup Pumping Facility (RMPF). The RMPF consists of a traveling screen intake structure, siltation basin, sharp crested weir, and 1200 cfs capacity pump station, once replacement pumps have been installed. The location of the existing screen intake structure is discussed in Subsection 1.2.4. All cooling system discharges from STP 3 & 4, including from the Ultimate Heat Sink (UHS), which is comprised of mechanical draft cooling towers, will be discharged to the MCR via a new discharge structure that will be built in the vicinity of STP 1 & 2 discharge structure. Water from the MCR would be discharged to the Colorado River in the future as necessary, based on the level and water quality of the MCR. Discharge of water to the Colorado River from the MCR would occur through the existing blowdown facility. Blowdown from the MCR to the Colorado River would occur as necessary to maintain the MCR water quality at an average of 3000 micro-Siemens per centimeter ( $\mu\text{S}/\text{cm}$ ) (Reference 2.3.3-1). The current Texas Pollution Discharge Elimination System (TPDES) permit (Reference 2.3.3-1) allows an average MCR discharge rate of 144 mgd with a daily maximum of 200 mgd. The permitted pH range for water discharged from the MCR is between 6.0 and 9.0 standard units. The water temperature daily average limit is 95°F with a daily maximum of 97°F. The total residual chlorine daily maximum is 0.05 mg/L. Any blowdown would occur at the TPDES permitted outfall location in the southeastern portion of the MCR. However, the last time that blowdown from the MCR occurred was 1997.

As discussed in Subsection 2.3.1, aside from some small onsite areas of standing water, sloughs, site drainage features, and the West Branch of the Colorado River, the Colorado River is the primary surface water body that could be affected by construction and operation of STP 3 & 4. The quality of water from the Colorado River is sufficient for plant operations. Existing water treatment methods and procedures are adequate for plant water use purposes. Little Robbins Slough intercepts and drains water from the western portion of the STP site and flows generally southeast to an area comprised of wetlands and marshlands located between the STP site and Matagorda Bay.

The portion of the Colorado River adjacent to the STP site, Colorado River Segment 1401, has been classified by the Texas Commission on Environmental Quality (TCEQ) as Tidal (Reference 2.3.3-1). The closest surface water quality monitoring station to the STP site is located at the Lower Colorado River Authority's Selkirk Island monitoring station located approximately 2 miles downstream of FM 521 and approximately 1.5 miles east of the

southeast portion of the MCR. Water quality data for this station for the period from January 2000 through September 2006 is included in Table 2.3.3-1 (Reference 2.3.3-3). Based on the data available at this location, the water quality is sufficient for plant use and there appears to be no environmental stressors associated with the existing water quality.

Freshwater flow from the Colorado River is important to the health and biological diversity of Matagorda Bay. A consortium of state agencies led by the Lower Colorado River Authority (LCRA) and Texas Parks and Wildlife Department recently selected 25 parts per thousand as the “desired salinity” in the eastern arm of Matagorda Bay, downstream of the mouth of the diverted Colorado River (Reference 2.3.3-4). It was agreed that this level of salinity would provide a “refuge” or “sanctuary” for important finfish and shellfish, particularly the Eastern oyster. In addition, Texas Parks and Wildlife Department designated this eastern arm of Matagorda Bay a finfish and shellfish nursery, making it off limits to commercial fishing and commercial harvesting of oysters. Table 2.3.3-2 shows targeted Colorado River freshwater inflows by month. Computer modeling indicated that an average monthly inflow of 36,000 acre-feet would be required to maintain an average salinity of 25 parts per thousand in the nursery area (Reference 2.3.3-4). As can be seen in the data presented in Section 5.2, STP withdrawal from the Colorado River is not expected to adversely impact achievement of this average monthly inflow rate.

Water quality data, primarily for metals and salts, for two reservoir sampling events performed during 2006 is summarized in Table 2.3.3-3.

Additional surface water sampling at the STP site includes sampling for radionuclides as part of the site’s Radiological Environmental Monitoring Program (REMP). Surface water samples from various locations in the vicinity of the site were analyzed for the radionuclides indicated in Table 2.3.3-4 during 2005. The results of the analytical testing indicated that tritium was the only radionuclide that tested above its lower detection limit. Out of the 12 samples tested for tritium, only 4 indicated the presence of tritium above detection limits. The sample location with the highest annual mean value was located in the south-southeast portion of the MCR near the blowdown discharge. The remainder of the radionuclides analyzed (40 samples) were not detected above their lower detection limits.

In addition to the sampling locations included in the REMP, there were historical sampling events for tritium at other locations. Water bodies sampled have included the west branch of the Colorado River, Little Robbins Slough, the east branch of Little Robbins Slough, an onsite ditch northeast of the MCR, and the MCR. The tritium data for these water bodies is summarized in Table 2.3.3-5. Sampling results indicate the presence of tritium in all six of the surface water body locations analyzed. Tritium was also detected in pressure relief wells (Table 2.3.3-6) installed within the above grade MCR dike. All measured tritium concentrations were below the U.S. Environmental Protection Agency’s primary drinking water standard of 20,000 picoCuries per liter. Since the relief wells discharge to the surface ditches around the dike, the results of the tritium analyses for these wells is considered surface water data.

Segment 1401 water uses support aquatic life, contact recreation, general use, and fish consumption. In 2004, Segment 1401 was assessed as “fully supported” for aquatic life, contact recreation, and for general uses. Fish consumption was not assessed (Reference 2.3.3-2). The draft 2006 water body assessment list shows the segment as not supporting contact recreational

use due to the presence of the bacteria *enterococcus* (Reference 2.3.3-5). *Enterococcus* is normally found in human and animal waste (Reference 2.3.3-6). Water quality associated with bacteria generally deteriorates during periods of heavy precipitation. Runoff from livestock producing facilities could carry increased amounts of bacteria which could then be carried to the nearest surface water feature. Heavy rains could also tax wastewater treatment facilities by flooding the systems and flushing water not yet fully treated to surface water features for transport downstream. Since there had been no release of water to the Colorado River from STP 1 & 2 operations, the STP site would not be considered a potential source of the bacteria. However, water pumped from the Colorado River to the MCR could also transport bacteria, which would be removed from the water stream during the water treatment process.

### **2.3.3.2 Groundwater**

Groundwater quality in the Gulf Coast Aquifer generally varies with depth and location. Water quality is good in terms of dissolved solids in the central and northeastern parts of the aquifer where the aquifer contains less than 500 milligrams per liter (mg/L) of total dissolved solids, but declines to the south where the total dissolved solids range from 1000 to more than 10,000 mg/L (Reference 2.3.3-7). Groundwater becomes more saline in the deeper subsurface and in discharge areas due to the long groundwater residence times and continued reaction with the aquifer minerals (Reference 2.3.3-8). Groundwater salinity is a function of total dissolved solids concentration. The salinity scale is as follows: fresh water (less than 1000 mg/L), slightly saline (1000 to 3000 mg/L) moderately saline (3000 to 10,000 mg/L), very saline (10,000 to 35,000 mg/L), and brine (greater than 35,000 mg/L) (Reference 2.3.3-8).

The aquifer of interest at the STP site is the Chicot Aquifer, which is the most shallow aquifer in the Gulf Coast Aquifer system. At the STP site, underlying aquifers within the Gulf Coast Aquifer System include the Evangeline, Jasper, and Catahoula Aquifers (Reference 2.3.3-8). The upper portion of the Chicot Aquifer is comprised of the Beaumont Formation.

The TCEQ is the entity responsible for protecting the state's groundwater quality. To this end, the TCEQ has implemented a comprehensive statewide groundwater management policy of antidegradation and has instituted a groundwater quality assessment program that maintains a network designed to monitor the ambient groundwater quality of nine major aquifer systems in Texas. One of these nine aquifer systems, the Chicot Aquifer (part of Gulf Coast Aquifer system), underlies the STP site.

Radionuclides, including uranium, radium, and radon gas are naturally occurring within the central and northeastern portion of the Gulf Coast Aquifer, with a high occurrence in the Harris County area located northeast of Matagorda County (Reference 2.3.3-7).

Groundwater quality data from wells within 6 miles (9.6 kilometers) of the STP site located in the same portion of the Chicot Aquifer as the STP site wells are summarized in Table 2.3.3-7. The locations of the wells are indicated on Figure 2.3.2-1.

In 2005, sample analyses on 26 groundwater samples from drinking water wells included in the REMP were analyzed for radionuclides. The results are included in Table 2.3.3-8. The results indicated that Gross Beta was the only radionuclide detected above laboratory detection levels. The control station for the sampling event had higher results than the STP site samples. The location with the highest annual mean Gross Beta concentration was 14 miles (22.4 kilometers)

north-northeast of STP 1 & 2. The elevated levels reflect natural radioactive material in the well water, activity not related to the STP site operations.

In 2005, sample analyses on six groundwater samples from monitoring wells included in the REMP were analyzed for the radionuclides. The results are included in Table 2.3.3-9 Tritium was the only radionuclide detected above laboratory detection levels. The location with the highest annual mean tritium concentration was directly south of, and adjacent to, the MCR, 3.8 miles south of STP 1 & 2.

In 2006, sample analyses on 16 groundwater samples from monitoring wells included in the REMP were analyzed for tritium. The results, as shown in Table 2.3.3-10, indicated levels above detection limits at only one groundwater sampling location, piezometer well number 435-02. This well is located approximately 700 feet west of the MCR embankment, approximately 2.9 miles (4.6 kilometers) southwest of STP 1 & 2.
