REPRINTED NOVEMBER 1986

NOTICE

Availability of Reference Materials Cited in NRC Publications

Most documents cited in NRC publications will be available from one of the following sources:

1. The NRC Public Document Room, 1717 H Street, N.W.
   Washington, DC 20555
2. The Superintendent of Documents, U.S. Government Printing Office, Post Office Box 37082,
   Washington, DC 20013-7082
3. The National Technical Information Service, Springfield, VA 22161

Although the listing that follows represents the majority of documents cited in NRC publications, it is not intended to be exhaustive.

Referenced documents available for inspection and copying for a fee from the NRC Public Document Room include NRC correspondence and internal NRC memoranda; NRC Office of Inspection and Enforcement bulletins, circulars, information notices, inspection and investigation notices; Licensee Event Reports; vendor reports and correspondence; Commission papers; and applicant and licensee documents and correspondence.

The following documents in the NUREG series are available for purchase from the GPO Sales Program: formal NRC staff and contractor reports, NRC-sponsored conference proceedings, and NRC booklets and brochures. Also available are Regulatory Guides, NRC regulations in the *Code of Federal Regulations,* and *Nuclear Regulatory Commission Issuances.*

Documents available from the National Technical Information Service include NUREG series reports and technical reports prepared by other federal agencies and reports prepared by the Atomic Energy Commission, forerunner agency to the Nuclear Regulatory Commission.

Documents available from public and special technical libraries include all open literature items, such as books, journal and periodical articles, and transactions. *Federal Register* notices, federal and state legislation, and congressional reports can usually be obtained from these libraries.

Documents such as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings are available for purchase from the organization sponsoring the publication cited.

Single copies of NRC draft reports are available free, to the extent of supply, upon written request to the Division of Technical Information and Document Control, U.S. Nuclear Regulatory Commission, Washington, DC 20555.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at the NRC Library, 7920 Norfolk Avenue, Bethesda, Maryland, and are available there for reference use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from the American National Standards Institute, 1430 Broadway, New York, NY 10018.

First through Sixth Annual Reports of the Operation of the U.S. AEC's Centralized Ionizing Radiation Exposure Records and Reports System, U.S. Atomic Energy Commission.

NUREG-75/108 Seventh Annual Occupational Radiation Exposure Report for Certain NRC Licensees - 1974, U.S. Nuclear Regulatory Commission, October 1975.

NUREG-0119 Eighth Annual Occupational Radiation Exposure Report for 1975, U.S. Nuclear Regulatory Commission, October 1976.

NUREG-0322 Ninth Annual Occupational Radiation Exposure Report for 1976, U.S. Nuclear Regulatory Commission, October 1977.

NUREG-0463 Tenth Annual Occupational Radiation Exposure Report for 1977, U.S. Nuclear Regulatory Commission, October 1978.

NUREG-0593 Eleventh Annual Occupational Radiation Exposure Report for 1978, U.S. Nuclear Regulatory Commission, January 1981.

NUREG-0714 Vol. 1 Twelfth Annual Occupational Radiation Exposure Report for 1979, U.S. Nuclear Regulatory Commission, August 1982.

NUREG-0714 Vols. 2 and 3 Occupational Radiation Exposure, Thirteenth and Fourteenth Annual Reports, 1980 and 1981, U.S. Nuclear Regulatory Commission, October 1983.

NUREG-0714 Vols. 4 and 5 Occupational Radiation Exposure, Fifteenth and Sixteenth Annual Reports, 1982 and 1983, U.S. Nuclear Regulatory Commission, October 1985.

EDITOR'S NOTE

For the past 10 years, the NRC has published two annual reports that summarized occupational radiation exposure data reported by certain types of NRC licensees. Each report has kept its same report number since 1979. NUREG-0713, Vols. 1 through 5, contained data reported by commercial nuclear power facilities only. NUREG-0714, Vols. 1 through 5, contained exposure information reported by several different types of NRC licensees. As a cost-reduction measure, these two reports are now being combined into one document, NUREG-0713, Vol. 6. From this time forward, the data that would have been presented in NUREG-0714 will be contained in subsequent volumes of NUREG-0713; additional volumes of NUREG-0714 will not be published. It is hoped that this change will not cause any confusion.

ABSTRACT

This report summarizes the occupational exposure data that are maintained in the U.S. Nuclear Regulatory Commission's Radiation Exposure Information and Reports System (REIRS). The bulk of the information contained in the report was extracted from the 1984 annual statistical reports submitted by seven categories* of NRC licensees subject to the reporting requirements of 10 CFR §20.407. These seven categories of licensees also submit personal identification and exposure information for terminating employees pursuant to 10 CFR §20.408, and some analysis of these "termination" data are also presented in this report.

Annual reports for 1984 were received from a total of 504 NRC licensees, 88 of whom were licensed nuclear power reactors. Compilations of these reports indicated that some 193,200 individuals were monitored, 108,500 of whom received a measurable dose. The collective dose incurred by these individuals was calculated to be 59,400 person-rems (person-cSv)** which represents a slight (4%) increase over the 1983 value. Since the number of workers receiving a measurable dose increased by 13%, the average measurable dose decreased to 0.55 rem (cSv).

About 20% of the monitored individuals were found to have received doses greater than 0.50 rem (cSv) as had been the case in the previous three years. However, the number of individuals receiving doses greater than five rems (cSv) continued to decrease.

Some 230,000 termination reports were submitted to the NRC which contained personal identification and exposure information for about 67,500 individuals who had completed their work assignment or employment with a covered category of NRC licensees during 1984. This is about the same as the number of persons terminating during each of the previous two years. The total number of monitored individuals for whom personal identification and exposure information has been incorporated into REIRS during the 16 years that it has been operating is now about 350,000, some 300,000 of whom terminated from nuclear power facilities.

Analyses of these data indicate that about 6,000 individuals completed work assignments at two or more nuclear reactor facilities during calendar year 1984 and received an average dose of 0.91 rem (cSv). Approximately 2,000 of these individuals worked at two or more reactor facilities during one calendar quarter and received an average dose of 0.40 rem (cSv). Both averages declined somewhat from those found for 1983. However, these figures may have to be revised because the termination data for about 15% of the individuals terminating during 1984 or 1983 were not computerized by the date of this publication.

---

*Commercial nuclear power reactors; industrial radiographers; fuel processors, fabricators, and reprocessors; manufacturers and distributors of byproduct material; independent spent fuel storage installations; facilities for land disposal of low-level waste; and geologic repositories for high-level waste.

**In the International System of Units the sievert (Sv) is the name given to the units for dose equivalent. One centisievert (cSv) equals one rem; therefore, person-rem becomes person-cSv.

PREFACE

A number of NRC Licensees have inquired how occupational radiation exposure data (from reports required by the NRC) are used by the NRC staff. This is a very appropriate inquiry that may be of importance to many affected licensees. In combination with other sources of information, the principal uses of the data are to provide facts regarding routine occupational exposures to radiation and radioactive material that occur in connection with certain NRC-licensed activities, including individual and collective radiation doses from external sources as well as pertinent information on the inhalation of radioactive material (nuclides involved, bioassay results, exposure magnitude, etc.). These facts are used by the NRC staff as indicated below:

1. The data permit evaluation, from the viewpoint of trends, of the effectiveness of the overall NRC/licensee radiation protection and ALARA efforts by certain licensees. They also provide for the identification (and subsequent correction) of unfavorable trends.

2. The external-dose data permit evaluation of the radiological risk associated with certain categories of NRC-licensed activities, including the size of the workforce and the collective dose.

3. The data provide for governmental monitoring of the potential transient-worker problem.

4. The data are used in the establishment of priorities for the utilization of NRC health physics resources: research, standards development, and regulatory program development.

5. The data are considered in reviews of inspection frequencies that are programmed for various categories of licensees.

6. The data may influence licensing action decisions.

7. The data are used for comparative analyses of radiation protection performance: US/foreign, BWRs/PWRs, civilian/military, plant/plant, nuclear industry/other industries, etc.

8. The data are used for justification of the expenditure of resources in the annual budget process.

9. The data help provide facts for evaluating the adequacy of the current risk-limitation system (e.g., are individual lifetime dose limits, worker population collective dose limits, and requirements for optimization needed?).

10. The data permit comparisons of occupational radiation risks with potential public risks when action for additional protection of the public involves worker exposures.

11. The data help in the evaluation of the effectiveness of dose-reduction measures (e.g., methods for reducing individuals' doses that may increase the collective dose).

12. The data provide facts for answering Congressional and Administration inquiries and for responding to questions raised by public interest groups, special interest groups, labor unions, etc.

13. The data provide information that can be used in the planning of epidemiological studies.

With regard to routine workplace conditions, the annual statistical summary reports required by § 20.407, the termination reports required by § 20.408, and the annual dose data reported by work function in accordance with Subsection 6.9.1.5 of the standard technical specifications for nuclear power plants provide the only centralized data base available to assist the staff in the performance of its duties as listed above. It is to everyone's advantage if these duties are performed by a well-informed staff in the light of factual information.

Robert E. Alexander, Chief
Safety Research Applications Branch

Occupational Radiation Exposure
at Commercial Nuclear Power Reactors and Other Facilities
Seventeenth Annual Report, 1984

1 INTRODUCTION

One of the basic purposes of the Atomic Energy Act and the implementing regulations in Title 10, Code of Federal Regulations, Chapter I, Part 20, is to protect the health and safety of the public, including the employees of the licensees conducting operations under those regulations. Among the regulations designed to ensure that the standards for protection against radiation set out in 10 CFR Part 20 are met, is a requirement that licensees provide individuals likely to be exposed to radiation with devices to monitor their exposure. Each licensee is also required to maintain indefinitely records of the results of such monitoring. However, there was no initial provision that these records or any summary of them be transmitted to a central location where the data could be retrieved and analyzed.

On November 4, 1968, the U.S. Atomic Energy Commission (AEC) published an amendment to Part 20 requiring the reporting of certain occupational radiation exposure information to a central repository at AEC Headquarters. This information was required of the four categories* of AEC licensees that were considered to involve the greatest potential for significant occupational doses and of AEC facilities and contractors exempt from licensing. A procedure was established whereby the appropriate occupational exposure data were extracted from these reports and entered into the Commission's Radiation Exposure Information Reporting System (REIRS), a computer system maintained at the Oak Ridge National Laboratory Computer Technology Center in Oak Ridge, Tennessee. The computerization of these data ensured that they would be kept indefinitely and facilitated their retrieval and analysis. The data maintained in REIRS have been summarized and published in a report every year since 1969. Annual reports for each of the years 1969 through 1973 presented the data reported by both AEC licensees and contractors and were published in six documents designated as WASH-1350-R1 through WASH-1350-R6.

In January 1975, with the separation of the AEC into the Energy Research and Development Administration (ERDA) and the U.S. Nuclear Regulatory Commission (NRC), each agency assumed responsibility for collecting and maintaining occupational radiation exposure information reported by the facilities under its jurisdiction. The annual reports published by the NRC on occupational exposure for calendar year 1974 and subsequent years do not contain information pertaining to ERDA facilities or contractors. Comparable information for facilities and contractors under ERDA, now the Department of Energy (DOE), is collected and published by DOE's Division of Operational and Environmental Safety at Germantown, Maryland.

---

*Commercial nuclear power reactors; industrial radiographers; fuel processors, fabricators, and reprocessors; and manufacturers and distributors of specified quantities of byproduct material.

In 1982 and 1983, paragraph 20.408(a) was amended to require three additional categories of NRC licensees to submit annual statistical exposure reports and individual termination exposure reports. The new categories are (1) geologic repositories for high-level radioactive waste, (2) independent spent fuel storage installations, and (3) facilities for the land disposal of low-level radioactive waste. Therefore, this document presents the exposure information that was reported by NRC licensees representing two of these new categories. (There are no geologic repositories for high-level waste currently licensed.)

This report and each of its predecessors summarizes information reported during previous years. However, more licensee-specific data, such as the annual reports submitted by each commercial power reactor pursuant to 10 CFR § 20.407 and their technical specifications, may be found in those documents listed on the inside of the front cover of this report. Additional operating data and statistics for each power reactor for the years 1973 through 1982 may be found in a series of reports, "Nuclear Power Plant Operating Experience" [Refs. 1-9]. These documents are available for viewing at all NRC public document rooms, or they may be purchased from the National Technical Information Service, as shown in the Reference section.

2 LIMITATIONS OF THE DATA

All of the figures compiled in this report relating to exposures and doses are based on the results and interpretations of the readings of various types of personnel monitoring devices employed by each licensee. This information obtained from routine personnel monitoring programs is sufficient to characterize the radiation environment in which individuals work and is used in evaluating the radiation protection program.

Monitoring requirements are based, in general, on 10 CFR § 20.202, which requires licensees to monitor individuals who receive or are likely to receive a dose in any calendar quarter in excess of 25% of the applicable quarterly limits. For most adults the quarterly limit for the whole body is 1.25 rems (cSv), so 0.312 rem (cSv) per quarter is the level above which monitoring is required. Depending on the administrative policy of each licensee, persons such as visitors and clerical workers may also be provided with monitoring devices for identification or convenience, although the probability of their being exposed to measurable levels of radiation is extremely small. Licensees are given the option of reporting the dose distribution of only those individuals for whom monitoring is required, or the dose distribution of all those for whom monitoring is provided. Many licensees elect to report the latter; however, this may increase the number of individuals that one could consider to be radiation workers. In an effort to account for this, the number of individuals reported as having "no measurable exposure" has been subtracted from the total number of individuals monitored in order to calculate an average dose per individual receiving a measurable dose, as well as the average dose per monitored individual.

One source of error that is present in the calculation of the annual collective dose (i.e., the summation of each monitored person's whole body dose) incurred by workers is the assumption that the midpoint of the dose range is the mean dose of the individuals reported in each dose range. This allows the collective dose to be calculated without knowing each person's actual annual dose. Past experience has shown that the actual mean dose of the individuals reported in each range is less than the midpoint. Thus, the collective doses presented in this report may be 10% higher than the sum of the actual individual doses.

The average dose per individual, as well as the dose distributions shown for groups of licensees, also could have been affected by the multiple reporting of individuals who were monitored by two or more licensees during the year. Since individuals are not identified in the annual reports, an individual who was monitored by five different licensees would have been counted once on each report. Therefore, when the data were summed to determine the total number of individuals monitored by a group of licensees, this person would be counted as five individuals rather than as one. This could also affect the distribution of doses because the individual has been counted five times in the lower dose ranges rather than one time in the higher range in which his actual accumulated dose (the sum of his doses incurred at each facility) would have placed him. This source of error has the greatest potential impact on the data reported by power reactor facilities since they employ many short-term workers. Further discussion of this is provided in Section 5.

Another fact that should be kept in mind before drawing any conclusions from the annual statistical data is that all of the personnel included in the reports may not have been monitored throughout the entire year. Many licensees such as radiography firms and nuclear power facilities may monitor numerous individuals for periods much less than a year. The average doses calculated from these data, therefore, are less than the average dose that an individual would receive if he were involved in that activity for the full year.

3 ANNUAL PERSONNEL MONITORING REPORTS - 10 CFR § 20.407

3.1 Definition of Terms and Sources of Data

3.1.1 Statistical Summary Reports

On February 4, 1974, 10 CFR § 20.407 was amended to require certain categories of licensees to submit an annual statistical report indicating the distribution of the whole body doses incurred by individuals whom they monitored for exposure to radiation. Table 3.2 shows the eighteen dose ranges specified by 10 CFR § 20.407(b) among which the doses are to be distributed. In prior years, the annual report was formatted differently and was not very useful as a basis for estimating the collective dose.

3.1.2 Number of Monitored Individuals

This is the total number of individuals that the NRC licensees covered by 10 CFR § 20.407 reported as being monitored for exposure to external radiation during the year. This number must include all individuals for whom monitoring is required, and may include visitors, service representatives, contract workers, clerical workers and any other individuals for whom the licensee feels that monitoring devices should be provided.

3.1.3 Number of Workers with Measurable Doses

The number of workers with measurable doses is obtained from the annual dose distribution reports submitted by NRC licensees pursuant to 10 CFR § 20.407 by subtracting the number of individuals having less than measurable doses from the total number of monitored individuals. This figure is used to calculate an individual's average measurable dose because it deletes those individuals who received exposures too small to be detected by personnel monitoring devices, many of whom probably did not routinely work in radiation areas (and were monitored for convenience or for identification purposes).

3.1.4 Collective Dose

The collective dose is used in this report to mean the summation of the whole body external dose received by each monitored individual and has the units person-rems (person-cSv).† The collective dose is not usually provided in the annual dose distribution reports submitted pursuant to 10 CFR § 20.407, but NRC staff

---

†In the International Systems of Units, the sievert (Sv) is the name given to the units for dose equivalent. One centisievert (cSv) equals one rem; therefore person-rems become person-cSv.

*Commercial nuclear power reactors; industrial radiographers; fuel processors, fabricators and reprocessors; manufacturers and distributors of byproduct material; independent spent fuel storage installations; and facilities for land disposal of low-level radioactive waste.

calculated it from the reports by summing the products obtained by multiplying the number of individuals reported in each of the dose ranges (shown in Table 1) by the midpoint of the corresponding range. This assumes that the midpoint of the range is equal to the arithmetic mean of the individual doses in the range. Past experience has shown that the actual mean dose of individuals reported in each dose range is less than the midpoint of the range, and the collective doses shown in this report for these may be about 10% too high. In 1981, a few power reactor licensees began reporting the actual collective dose (as determined from official personnel dosimetry results) on their § 20.407 annual reports, and the NRC staff used these doses, when provided, instead of the above-described calculations. The staff would prefer to use the actual collective dose and encourages more licensees to make it available.

3.1.5 Average Individual Dose

The average individual dose is obtained by dividing the collective dose by the total number of individuals reported as being monitored. This figure is usually less than the average measurable dose because it includes the number of those individuals who received zero or less than measurable doses.

3.1.6 Average Measurable Dose

The average measurable dose is obtained by dividing the collective dose by the number of workers that received a measurable dose. This is the average most commonly used in this and others' reports when examining trends and comparing doses received by workers in various segments of the nuclear industry because it reflects the deletion of those individuals receiving zero or minimal doses, many of whom were monitored for convenience.

3.1.7 Number of Licensees Reporting

This is the number of NRC licenses issued to companies to use radioactive material for certain activities that would place them in one of the six categories that are required to report pursuant to 10 CFR § 20.407. The third column in Table 3.1 shows the number of licensees that have filed such reports during the last several years. State licensees do not submit such reports to the NRC.

3.1.8 CR

One of the parameters that the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) recommends be calculated for occupational dose distributions to aid in the comparison of exposure data is a ratio "CR." CR is defined to be the ratio of the annual collective dose incurred by individuals whose annual doses exceed 1.5 rems to the total annual collective dose. One UNSCEAR report [Ref. 10] states that normal values of CR should be between 0.05 and 0.50. This means that, usually, no more than 50% of the collective dose should be due to individual doses that exceed 1.5 rems. The last column in Table 3.1 shows the values of CR for the different types of licenses; one can see that CR is close to 0.50 for three of the categories and is much less than 0.50 for the remaining three categories for 1984.

Table 3.1
ANNUAL EXPOSURE DATA FOR CERTAIN CATEGORIES OF LICENSEES
1973 - 1984

License Category	Calendar Year	Number of Licensees Reporting	Number of Monitored Individuals	Number of Workers with Measurable Doses	Collective Dose (person-rems or person-cSv)	Average Individual Dose (rems or cSv)	Average Measurable Dose per Worker (rems or cSv)	CR+

+CR is the ratio of the annual collective dose delivered at annual doses exceeding 1.5 rems to the total annual collective dose. (See Section 3.1).
*These figures are adjusted to account for the multiple counting of transient reactor workers (see Section 5).
**Includes all LWRs that reported, although all of them may not have been in commercial operation for a full year, but excludes the gas-cooled reactor.

3.2 Annual Whole Body Dose Distributions

Table 3.2 is a compilation of the statistical summary reports submitted by six categories of licensees. One can see that in nearly every category some 40%-70% of the doses are less than measurable. About 90% of the reported individuals were monitored by nuclear power facilities where they received about 90% of the total collective dose in 1984.

The "Adjusted Total" shown in Table 3.2 for the dose distribution of individuals monitored by commercial power reactors in 1984 reflects corrections that were made to the compilation of the annual reports to account for the counting of transient workers more than one time. This adjusted total was also used in the calculation of the "Grand Total" at the bottom of the table. Further discussion of the data and methodology used in making these corrections is given in Section 5.

It should be pointed out that annual exposures that exceed five rems (cSv) are not necessarily classified as personnel overexposures. Although 1.25 rems (cSv) is the quarterly limit set forth in paragraph (a) of 10 CFR § 20.101, paragraph (b) permits licensees, under certain conditions, to allow a worker to receive a whole body dose of three rems (cSv) per calendar quarter (up to 12 rems (cSv)) annually. The conditions are that the licensee must have determined and recorded the worker's prior accumulated occupational dose to the whole body and that the worker's whole body dose when added to his accumulated occupational dose does not exceed 5(N - 18) rems (cSv), where N equals the individual's age in years. Although there is no annual limit, annual exposures that exceed 12 rems (cSv) indicate that an overexposure has occurred. Any quarterly exposure in excess of the applicable quarterly limits must be reported. A discussion of various types of occurrences in which the limits have been exceeded is given in Section 6.

A summary of the annual whole body exposures reported to the Commission by certain categories of NRC licensees required to submit reports pursuant to 10 CFR § 20.407 during the past 16 years is presented in Table 3.3. About 95% of the exposures have consistently remained less than two rems (cSv), and the number of individuals receiving an annual exposure in excess of five rems (cSv) has declined to remain at about one-tenth of one percent of the total number of individuals monitored each year for the last three years.

3.3 Summary of Occupational Exposure Data by License Category

3.3.1 Industrial Radiography Licenses, Single and Multiple Locations

These licenses are issued to allow the use of sealed radioactive materials, usually in exposure devices or "cameras," that primarily emit gamma rays for nondestructive testing of pipeline weld joints, steel structures, boilers, aircraft and ship parts, and other high-stress alloy parts. Some firms are licensed to conduct such activities in one location, usually in a plant, and others perform radiography at multiple sites in the field. As shown in Table 3.1, annual reports were received for 361 radiography licenses in 1984, which is about the same number as reported in 1982 and 1983.

Table 3.2

*Dose values exactly equal to the values separating ranges are reported in the next higher range.
**Includes all reactors that reported although all of them may not have been in commercial operation for a full year.
†These values are adjusted to account for the multiple counting of transient reactor workers, but the adjustment may not be complete because all of the 1984 termination data have not been computerized.

Table 3.3

SUMMARY OF ANNUAL DOSE DISTRIBUTIONS
FOR CERTAIN NRC LICENSEES

1968-1984

Year	Total Number of Monitored Persons Compiled Number	(Adjusted* Number)	Percent of Individuals With Doses <2 rems	Percent of Individuals With Doses >5 rems	Number of Individuals With Doses >12 rems
1968	36,836		97.2%	0.5%	3
1969	31,176		96.5%	0.5%	7
1970	36,164		96.1%	0.6%	0
1971	36,311		95.3%	0.7%	1
1972	44,690		95.7%	0.5%	8
1973	67,862		95.0%	0.5%	1
1974	85,097		96.4%	0.3%	1
1975	78,713		94.8%	0.5%	1
1976	92,773		95.0%	0.4%	3
1977	98,212	(93,438)	93.8%*	0.4%*	1
1978	105,893	(100,818)	94.6%*	0.2%*	3
1979	131,027	(125,316)	95.2%*	0.2%*	1
1980	159,177	(150,675)	94.6%*	0.3%*	0
1981	157,874	(149,314)	94.6%*	0.2%*	1
1982	162,456	(154,117)	94.9%*	0.1%*	0
1983	172,927	(164,239)**	94.6%*	0.1%*	0
1984	204,069	(194,840)**	95.91*	0.1%*	0

*Based on the distribution of individual doses after adjusting for the multiple counting of transient reactor workers (see Section 5).
**The termination data for about 15% of the individuals terminating during 1983 or 1984 have not been entered into the REIR System.

Table 3.4 summarizes the reported data for the two types of radiography licenses for 1984 and for the previous two years for comparison purposes. The table shows that both the number of workers (701) receiving measurable doses and the collective dose (196) of workers at the single-location facilities decreased by about 9%. This resulted in the average measurable dose remaining at 0.28 rem (cSv). The number of workers at firms having multiple-location licenses increased by about 8% while the collective dose increased only about 6%. This resulted in the average measurable dose decreasing slightly to 0.48 rem (cSv). Overall, one finds that the average measurable dose for radiography workers continues to remain at about 0.50 rem (cSv), as it has for the last eight years, and that the average dose for workers performing radiography at a single location is usually about half this amount. This is probably due to the fact that it is more difficult for workers to avoid exposure to radiation in the field, where conditions are not the best and may change every day. In order to see the contribution that each radiography licensee made to the total collective dose, a summary of the information reported by each of these licensees in 1984 is presented in alphabetical order in Appendix A.

Table 3.4

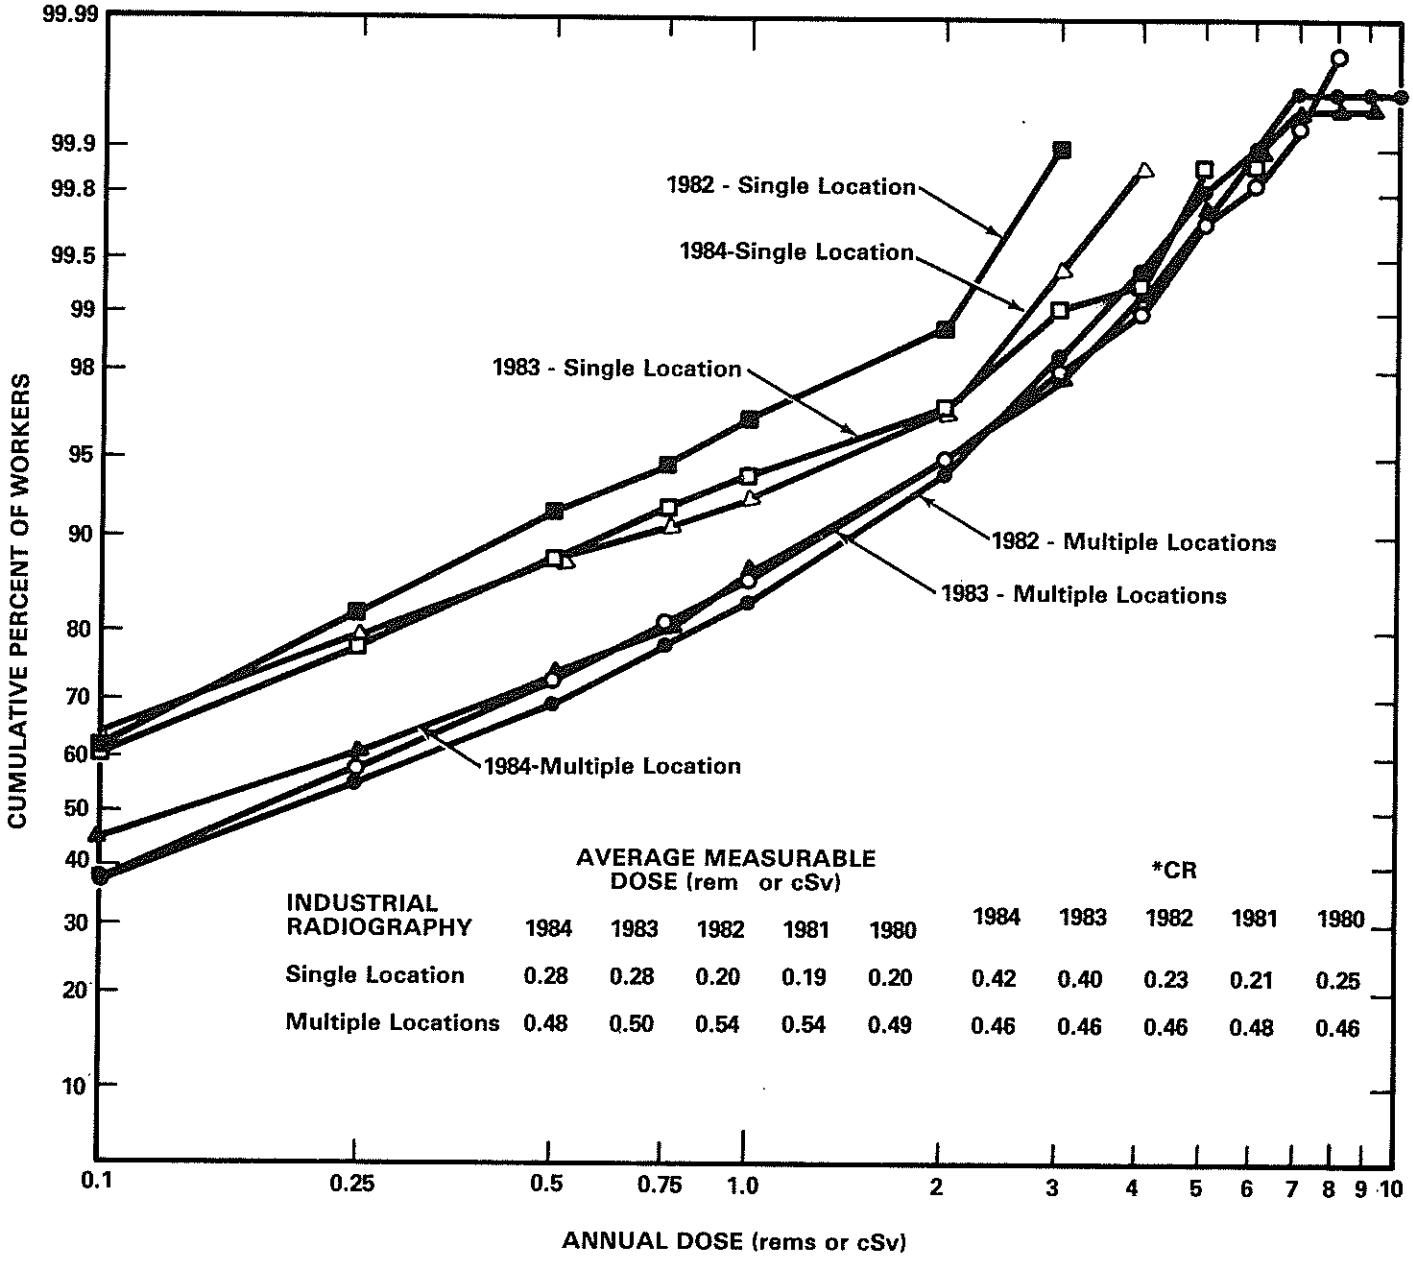
ANNUAL EXPOSURE INFORMATION FOR INDUSTRIAL RADIOGRAPHERS
1982-1984

Type of License	Year	No. of Licen-ses	Number of Monitored Individuals	Workers with Measurable Doses	Collective Dose (person-rems or person-cSv)	Average Measurable Dose (rems or cSv)
Single location		129	1,778	701	196	0.28
Multiple locations	1984	232	6,680	4,745	2,294	0.48
Total		361	8,458	5,446	2,490	0.46
Single location		128	1,714	773	213	0.28
Multiple locations	1983	210	6,910	4,358	2,171	0.50
Total		338	8,624	5,131	2,384	0.46
Single location		126	1,977	942	187	0.20
Multiple locations	1982	227	7,258	5,218	2,811	0.54
Total		353	9,235	6,160	2,998	0.49

Since personnel monitoring data has frequently been found to have log-normal distributions [Ref. 11], trends in the data reported by radiography licensees may be observed from log probability plots* of the data. Figure 3.1 displays such plots of the doses incurred by workers monitored by the two types of radiography licensees for each of the years 1982, 1983, and 1984. The plots of the dose distributions of workers at single-location radiography facilities, where the workers receive doses that are lower than those usually received by workers at multiple-location facilities, form fairly straight lines and usually lie above those of the multiple-location facilities. One feature of these types of graphs is that several comparisons of various dose distributions can be quickly made. For example, one can easily see that in 1984 about 85% of the workers monitored by firms licensed for radiography at multiple locations received doses that were less than one rem (cSv), while some 92% of the workers monitored at single location radiography facilities received such doses. Also, the relative positions and curvature of the graphs are indicative of certain characteristics of the dose distributions. For example, the position of the 1983 and 1984 plot of the dose distribution of workers at single-location facilities below that of the 1982 plot indicates an increase in the average dose and in CR (as shown at the bottom of the graph). This is due to the fact that there were more workers with doses that exceeded three rems (cSv) in 1983 and 1984. The 1984 plot of the multiple-location licensees is quite close to those for 1982 and 1983, and one finds similar average doses and values of CR each year.

*If the data have a log normal distribution, the data points will form a straight line when plotted on log probability paper on which cumulative probabilities are laid off on the vertical axis at distances proportional to the corresponding number of standard deviations above or below the median and the dose is plotted on the horizontal axis on a logarithmic scale.

Figure 3.1
ANNUAL DOSE DISTRIBUTION OF WORKERS
AT INDUSTRIAL RADIOGRAPHY FACILITIES
1982-1984



INDUSTRIAL RADIOGRAPHY	AVERAGE MEASURABLE DOSE (rem or cSv)					*CR				
	1984	1983	1982	1981	1980	1984	1983	1982	1981	1980
Single Location	0.28	0.28	0.20	0.19	0.20	0.42	0.40	0.23	0.21	0.25
Multiple Locations	0.48	0.50	0.54	0.54	0.49	0.46	0.46	0.46	0.48	0.46

*CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems to the total annual collective dose.

Note: Each point on the curves represents the cumulative percentage of workers with measurable doses who received doses less than the indicated annual dose.

The tendency of the plots to curve upward for doses greater than one rem (cSv) is typical of distributions having several workers with doses in the higher dose ranges [Refs. 10, 11], and indicates that the entire distribution is not a log-normal one. Another theoretical analysis of occupational dose distributions [Ref. 12] has found that these data may be fitted by a hybrid log-normal distribution. At low doses, this distribution is log normal, but at higher doses, where radiation control programs very closely monitor each worker's total dose so that the frequency of doses approaching the dose limits is reduced, the distribution is normal.

3.3.2 Manufacturer and Distributor Licenses, Broad and Other

These licenses are issued to allow the manufacture and distribution of radionuclides in various forms for a number of diverse purposes. Broad licenses are issued to large facilities having a comprehensive radiological protection program, and the other licenses are usually issued to smaller firms requiring a more restrictive license. Some firms are medical suppliers that process, package, or distribute such products as diagnostic test kits, radioactive surgical implants, and tagged radiochemicals for use in medical research, diagnosis, and therapy. Other firms are suppliers of industrial radionuclides and are involved in the processing, encapsulation, packaging, and distribution of the radionuclides that they have purchased in bulk quantities from production reactors and cyclotrons. Major products include gamma radiography sources, cobalt irradiation sources, well-logging sources, sealed sources for gauges and smoke detectors, and radiochemicals for nonmedical research. However, only those NRC licensees (about 35) that possess or use at any one time specified quantities of the nuclides listed in paragraph 20.408(a)(6) are required to submit annual (10 CFR § 20.407) and termination (10 CFR § 20.408) reports.

Table 3.5 presents the annual data that were reported by the two types of licensees for 1984 and the previous two years. The total number of workers receiving measurable doses as reported by these types of licensees continued to decline somewhat to 1,932 workers in 1984. The collective dose decreased by about 22% or 200 person-rems (person-cSv), and the average dose declined to 0.33 rem (cSv). This reduction was primarily due to the fact that one fairly large broad-scope licensee ceased its manufacturing and distribution activities. Looking at the information shown separately for the broad and other licensees, one can see that the values of all of the parameters remain higher for the broad licensees, probably because this type of license allows the possession of larger quantities of radioactive materials than do the other licenses. In order to see the contribution that each of these licensees made toward the total values of the number of persons monitored, number of workers, and collective dose, Appendix A lists the values of these parameters for each licensee in alphabetical order by licensee name for 1984.

Table 3.5

ANNUAL EXPOSURE INFORMATION FOR MANUFACTURERS AND DISTRIBUTORS
1982-1984

Type of License	Year	No. of Licen-sees	Number of Monitored Individuals	Workers with Measurable Doses	Collective Dose (person-rems or person-cSv)	Average Measurable Dose (rems or cSv)
M & D-Broad		13	4,625	1,716	594	0.35
M & D-Other	1984	25	384	216	48	0.22
Total		38	5,009	1,932	642	0.33
M & D-Broad		16	4,332	1,744	767	0.44
M & D-Other	1983	17	719	259	57	0.22
Total		33	5,051	2,003	824	0.41
M & D-Broad		18	4,610	1,892	821	0.43
M & D-Other	1982	16	843	307	69	0.22
Total		34	5,453	2,199	890	0.40

Figure 3.2 displays log probability plots of the doses incurred by workers under the two types of manufacturing and distribution licenses for the years 1982 through 1984. The position of the curves plotted for the other licenses above those plotted for the broad licenses indicates that a larger portion of the workers reported by the other licensees have lower doses than those reported by the broad licensees. For example, the graphs show that about 86% of workers monitored by the broad licensees received doses that were less than one rem (cSv), while about 95% of the workers monitored by the other licensees received such doses in 1984.

3.3.3 Low-Level Waste Disposal Licenses

These licenses are issued to allow the receipt, possession, and disposal of low-level radioactive wastes at a land disposal facility. The licensee has the appropriate equipment to pick up wastes from such places as hospitals and laboratories, and transport them to a proper facility for storage and burial.

The requirement for this category of NRC licensee to file annual reports became effective in January 1983. Two licensees in this category submitted annual reports in 1984, while in 1982 and 1983 there was only one licensee in this category. Table 3.1 summarizes the data reported for 1982 through 1984. In 1984, the total number of monitored individuals increased because a second licensee

Figure 3.2
ANNUAL DOSE DISTRIBUTION OF WORKERS
AT MANUFACTURING & DISTRIBUTION FACILITIES
1982-1984

	AVERAGE MEASURABLE DOSE (rem or cSv)					*CR				
MANUF. & DIST.	1984	1983	1982	1981	1980	1984	1983	1982	1981	1980
Broad	0.35	0.44	0.43	0.44	0.54	0.48	0.54	0.52	0.55	0.61
Other	0.22	0.22	0.22	0.17	0.13	0.20	0.20	0.38	0.33	0.27

*CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems to the total annual collective dose.

Note: Each point on the curves represents the cumulative percentage of workers with measurable doses who received doses less than the indicated annual dose.

was included in this category. However, the collective dose, 72 person-rems (person-cSv), remained about the same as that found for 1983 because the collective dose calculated for the one licensee that reported in 1983 declined by about the same amount as that calculated for the licensee included for the first time in 1984. The number of workers receiving measurable doses also decreased slightly so that the average measurable dose rose somewhat to 0.24 rem (cSv).

Figure 3.3 displays log probability plots of the doses incurred by workers at the low-level waste disposal facilities from 1982 through 1984. One can quickly see that the distributions are quite similar, with all of the doses being less than two rems (cSv) and about 90% of the doses being less than 0.75 rem (cSv) each year. However, the position of the plot for 1984 below that for 1983 is indicative of the slight increase in the average dose and CR. Appendix A summarizes the exposure information reported by these licensees in 1984.

3.3.4 Independent Spent Fuel Storage Installation Licenses

These licenses are issued to allow the possession of power reactor spent fuel and other associated radioactive materials for the purpose of storage of such fuel in an independent spent fuel storage installation (ISFSI). Here, the spent fuel, which has undergone at least one year of decay since being used as a source of energy in a power reactor, is provided interim storage, protection, and safeguarding for a limited time pending its ultimate disposal.

Table 3.1 summarizes the data submitted for 1982 through 1984 by the only licensed ISFSI. Only about 35 individuals have been monitored at the facility each year. However, in 1984 the collective dose increased by about 50% to a value of 13 person-rems (person-cSv). The average measurable dose also increased from 0.30 rem (cSv) to 0.41 rem (cSv). These increases were primarily due to a significant increase in the amount of incoming spent fuel in 1984.

Figure 3.3 displays log probability plots of the doses incurred by workers at the ISFSI for the years 1982 through 1984. The plots are quite similar for 1982 and 1983 when all doses were less than 0.75 rem so the value of CR was zero each year. The plot of the 1984 data lies below that of the previous two years, which indicates that there were doses in higher ranges than before, but all doses were less than 2 rems (cSv) as reflected in the low value (0.06) of CR.

3.3.5 Fuel Fabrication and Reprocessing Licenses

The fuel fabrication licenses are issued to allow the processing and fabrication of reactor fuels. In most uranium facilities where light water reactor fuels are processed, uranium hexafluoride enriched in the isotope U-235 is converted to solid uranium dioxide pellets and inserted into zirconium tubes. The tubes are fabricated into fuel assemblies, which are shipped to nuclear power plants. Some facilities also perform chemical operations to recover the uranium from scrap and other off-specification materials. On a much smaller scale, fuel assemblies containing plutonium oxide pellets can be similarly fabricated and used in reactors for experimental purposes. However, there are no NRC licensees engaged in this activity at this time.

The number of facilities licensed by the NRC to fabricate fuel, especially plutonium fuel, has been decreasing for the last several years (Table 3.1). Therefore, a number of licensees are primarily engaged in decommissioning activities,

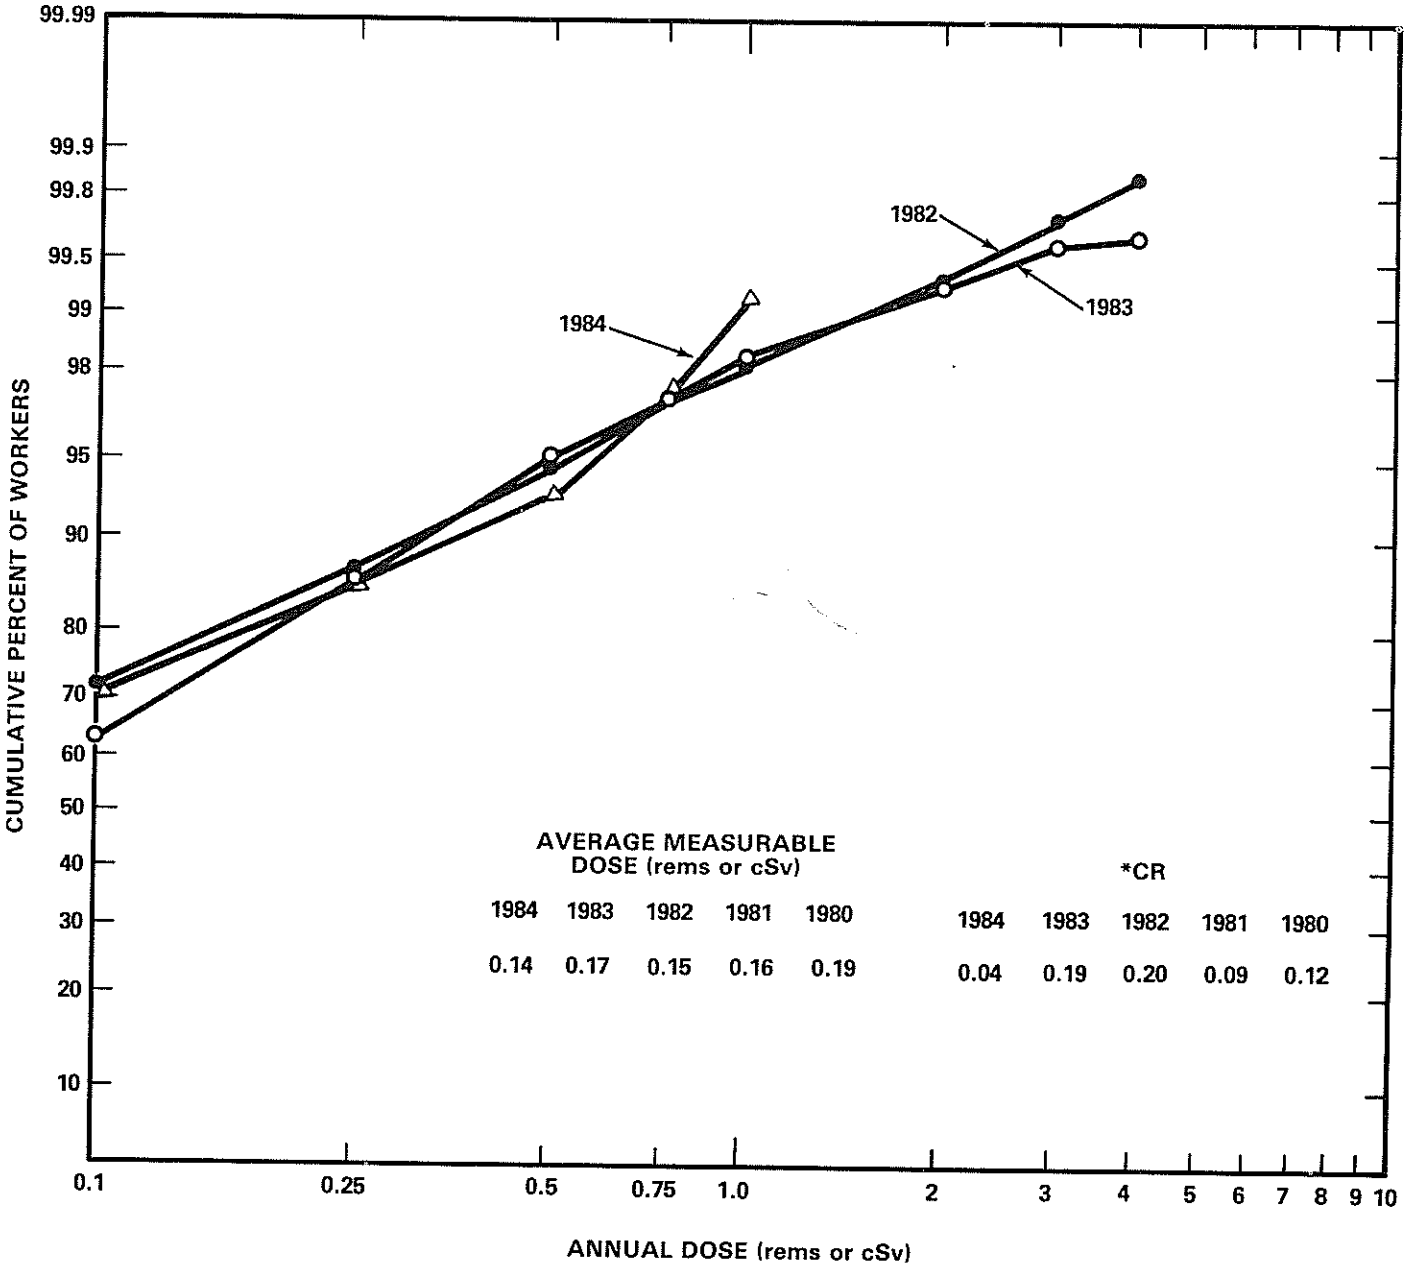
Total		14	9,488	5,772	818	0.14
Uranium Fuel Fab		11	8,440	4,746	748	0.16
Pu Decommissioning	1983	4	583	267	87	0.33
Total		15	9,023	5,013	835	0.17
Uranium Fuel Fab		11	8,652	5,117	724	0.14
Pu Decommissioning	1982	5	1,156	316	107	0.34
Total		16	9,808	5,433	831	0.15

Table 3.6 shows that the number of workers involved in decommissioning activities decreased sharply in 1984, as did the collective dose. The major reason for this is that there was one licensee involved in both decommissioning activities and the analysis of post-irradiated fuel in 1982 and 1983. The decommissioning is now complete and the licensee is no longer included in the fuel fabrication category. However, it should be pointed out that three of the eleven licensees primarily engaged in uranium fuel fabrication in 1982 and 1983 were also involved in the decommissioning of plutonium facilities, and the report submitted by each one covered both activities. Therefore, for comparison with data submitted for previous years, the data in the "Total" row should be used because decommissioning activities were also being conducted during previous years and were not shown separately. Appendix A lists the number of persons monitored, the number of workers receiving measurable doses, and the collective dose for each of these licensees in alphabetical order by licensee name for 1984.

Figure 3.4 consists of the log probability plots of the dose distributions of workers at fuel fabrication facilities for the years 1982 through 1984. The plots for 1982 and 1983 are quite similar, with all doses being less than five rems (cSv) and about 99.3% of the doses being less than two rems (cSv) each year. The average dose and the value of CR were therefore about the same for each year. However, in 1984, there were no doses greater than two rems (cSv) so that the value of CR fell to 0.04.

Figure 3.4
ANNUAL DOSE DISTRIBUTION OF WORKERS
AT FUEL FABRICATORS AND PROCESSORS
1982-1984



AVERAGE MEASURABLE DOSE (rems or cSv)					*CR				
1984	1983	1982	1981	1980	1984	1983	1982	1981	1980
0.14	0.17	0.15	0.16	0.19	0.04	0.19	0.20	0.09	0.12

*CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems to the total annual collective dose.

Note: Each point on the curves represents the cumulative percentage of workers with measurable doses who received doses less than the indicated annual dose.

Fuel reprocessing licenses are issued to allow the separation of usable uranium and plutonium from spent nuclear fuel. There was only one commercial facility that was ever licensed to reprocess fuel, and it has been shut down since 1972. However, the licensee did some decontamination work and stored radioactive waste at the facility for several years, and the annual report that was submitted each year was usually grouped with those of the fuel fabricators. In February 1982, the Department of Energy assumed possession and control of the reprocessing facility to conduct waste solidification activities necessary for final decommissioning. During this period, the NRC license will, in effect, be suspended, and no reports will be filed with the NRC.

3.3.6 Water-Cooled Power Reactor Licenses

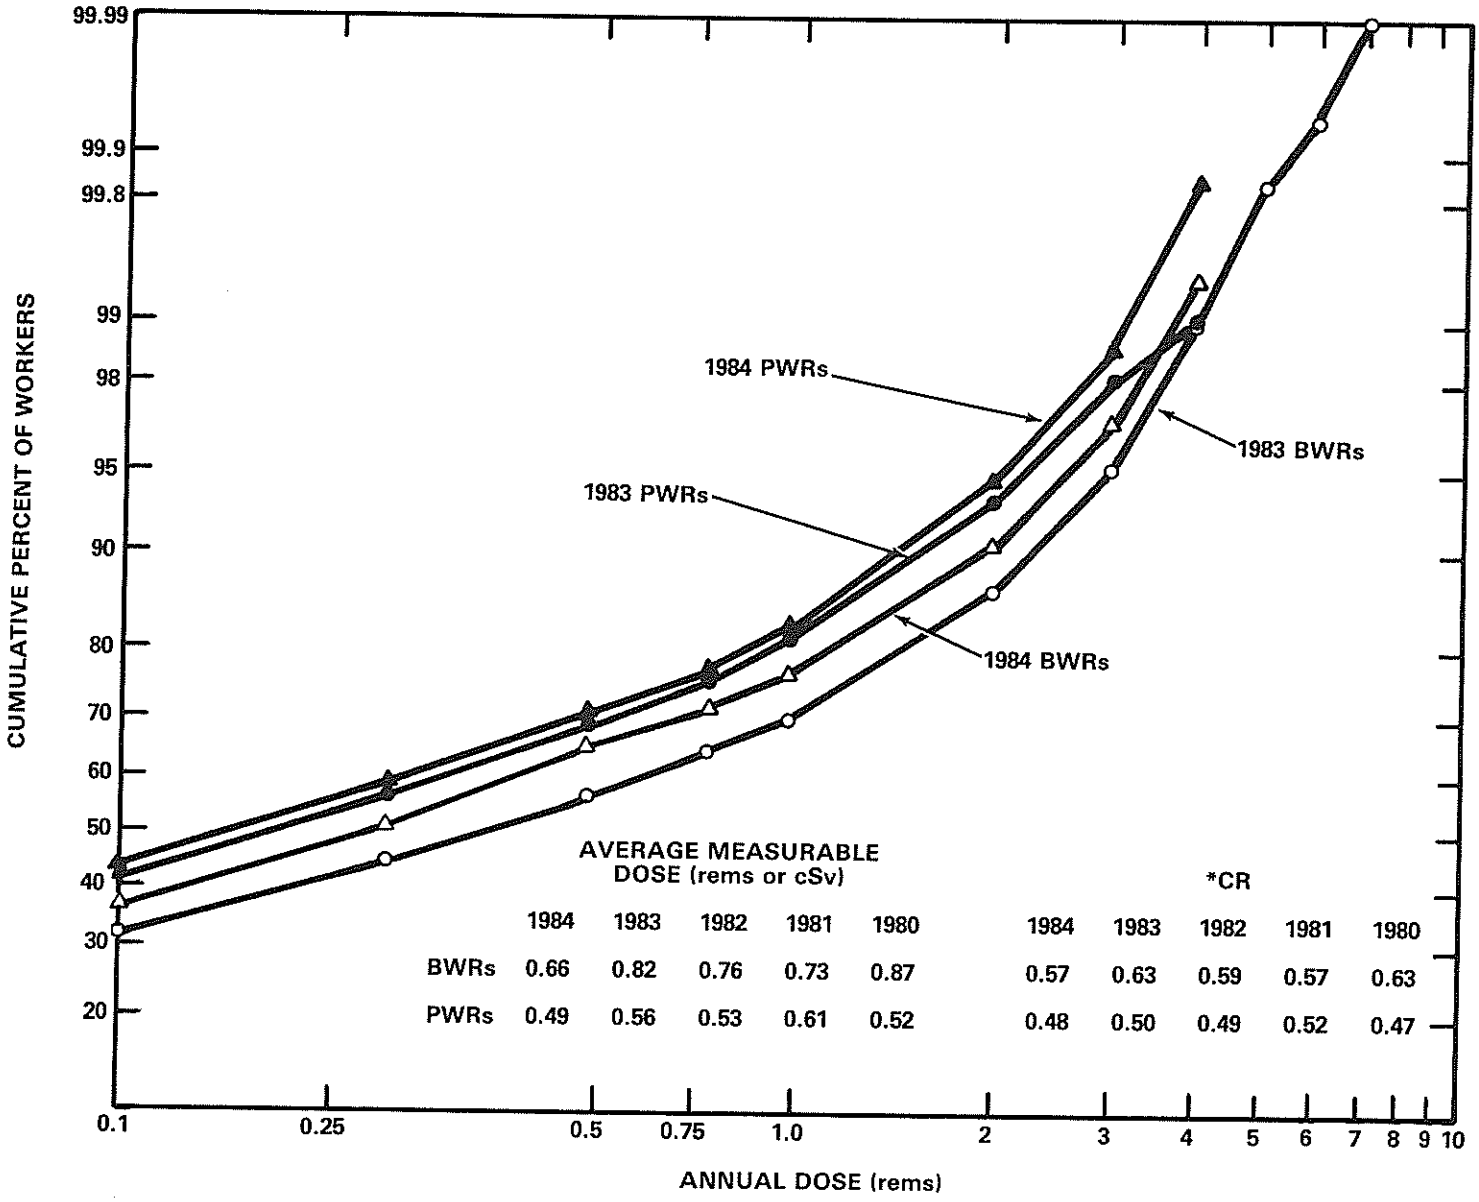
These licenses are issued to utilities to allow them to use special nuclear material in a reactor to produce heat to generate electricity to be sold to consumers. There are two major types of commercial reactors in the United States - pressurized water reactors (PWRs) and boiling water reactors (BWRs) - each of which uses water as the primary coolant.

As shown in Table 3.1, annual reports were received from nuclear power facilities for 88 licensed reactors where 169,242 individuals were monitored for exposure to radiation in 1984. Of this number 94,996 workers received a measurable dose and incurred a collective dose of 55,353 person-rems (person-cSv). It appears that the collective dose is beginning to level off or decrease somewhat, while the number of workers continues to increase. This has resulted in the average measurable dose decreasing to 0.58 rem (cSv). The dose distributions of workers monitored at each plant site is presented in alphabetical order by site name in Appendix B.

Figure 3.5 presents the log-normal plot of the distribution of the whole body doses received by radiation workers at nuclear power facilities in 1983 and 1984. One can quickly see that about 73% of the workers receiving measurable doses at BWRs received doses that were less than one rem (cSv) while about 82% of such workers at PWRs received doses of less than one rem (cSv). The position of the BWR plots below those of the PWRs each year indicates that higher average doses were received at BWRs. Also, departures from a straight line for doses that exceed one rem are again seen, and, according to the hybrid log-normal method [Ref. 12] of analyzing these dose distributions, the sharpness of the departure indicates that a strong feedback mechanism operates when workers begin to incur larger doses and may reflect efforts to keep doses as low as reasonably achievable [Ref. 13].

Listed at the bottom of the figure are the values of CR for the last five years. These show that a larger portion of the collective dose (about 60%) at BWRs continues to be due to workers receiving doses greater than 1.5 rems (cSv) than at PWRs, where CR is usually about 0.50. More detailed presentations and analyses of the annual exposure information reported by nuclear power facilities can be found in Section 4.

Figure 3.5
ANNUAL DOSE DISTRIBUTION OF WORKERS AT
LIGHT WATER REACTOR FACILITIES
1983 & 1984



AVERAGE MEASURABLE DOSE (rems or cSv)

	1984	1983	1982	1981	1980	*CR 1984	1983	1982	1981	1980
BWRs	0.66	0.82	0.76	0.73	0.87	0.57	0.63	0.59	0.57	0.63

*CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems to the total annual collective dose.

Note: Each point on the curves represents the cumulative percentage of workers with measurable doses who received doses less than the indicated annual dose.

3.3.7 High-Temperature Gas-Cooled Power Reactor Licenses

A license to operate a power reactor is issued to utilities to allow them to use special nuclear material in a reactor to produce heat to generate electricity to be sold to consumers. In this type of a reactor, a gas, usually helium, is used as the primary coolant. Fort St. Vrain near Greeley, Colorado, is the only such reactor in operation in the U.S. As shown in Table 3.7, annual whole body doses incurred by workers at the plant have been minimal. No one has ever exceeded an annual dose of 0.25 rem (cSv), and the average dose per worker is usually less than 0.05 rem (cSv).

Table 3.7

ANNUAL EXPOSURE INFORMATION FOR FORT ST. VRAIN
1974-1984

4 COMMERCIAL LIGHT WATER REACTORS - FURTHER ANALYSIS

4.1 Introduction

Since general trends in occupational radiation exposures at nuclear power reactors are best evaluated within the context of other pertinent information, some of the tables and appendices that summarize exposure data also show the type, capacity, and age of the reactor; the amount of electricity generated; the type of workers being exposed; and the sort of tasks being performed.

4.2 Definitions of Terms and Sources of Data

4.2.1 Number of Reactors

The number of reactors shown in Tables 4.1, 4.2, and 4.3 is the number of BWRs, PWRs, and total light-water-cooled reactors (LWRs), respectively, that had been in commercial operation for at least one full year as of December 31 of each of the indicated years. This is the number of reactors on which the average number of workers and average collective dose per reactor is based. Excluded are those reactors that may have been in commercial operation for only a few months during the first year, and conservative values are yielded for the averages. The date that each reactor was declared to be in commercial operation was found in Reference 14.

4.2.2 Electric Energy Generated

The electric energy generated in gross megawatt-years (MW-yr) each year by each facility is shown in Appendix C. This number was obtained by dividing the gross megawatt-hours of electricity annually produced by each facility by 8,760, the number of hours in the year, except for leap years when the number is 8,784 hours. The gross megawatt-years of generated electricity that are presented in Tables 4.1, 4.2, and 4.3 are the sums of that produced by the number of reactors included each year. These sums are divided by the number of those reactors included in each year to yield the average amount of electric energy generated (MW-yr) per reactor, which is also shown in Tables 4.1, 4.2, and 4.3. The number of gross megawatt-hours of electricity produced each year was also found in Reference 14.

4.2.3 Collective Dose per Megawatt-Year

The number of megawatt-years of electricity generated was used in determining the ratio of the average value of the annual collective dose to the number of megawatt-years of electricity generated. The ratio was calculated by dividing the total collective dose by the total gross megawatt-years generated and is a figure that is a measure of the dose incurred by workers at power plants in relation to the gross electric energy produced. This ratio was also calculated for each reactor site and is presented in Tables 4.1, 4.2, and 4.3 and Appendix C.

4.2.4 Average Rated Capacity

The average rated capacity, shown in Tables 4.1, 4.2, and 4.3 was found by dividing the sum of the net maximum dependable capacities (net MWe) of the reactors by the number of reactors included each year. The net maximum dependable capacity is defined to be the gross electrical output as measured at the

*Includes only those reactors that had been in commercial operation for at least one full year as of December 31 of each of the indicated years, and all figures are uncorrected for multiple reporting of transient individuals.

**Five plants have been shut down continuously for a number of years but the data they reported has been used in the compilation of various totals and averages shown in this report. One may wish to calculate these figures without including these reactors each year: Dresden 1 - shut down since 10/78; Humboldt Bay - shut down since 7/76; Indian Point 1 - shut down since 10/78; Three Mile Island 1 and 2 - shut down since 3/79. (See Appendix B)

†In 1984, it was decided that Humboldt Bay and Indian Point 1 would not be put in commercial operation again, and they are not included in compilations in this report.

output terminals of the turbine generator during the most restrictive seasonal conditions, less the normal station service loads. This "capacity" of each plant was found in Reference 14, and it is shown for each site in Appendix C.

4.3 Annual Whole Body Dose Distributions

Table 4.4 summarizes the distribution of the annual whole body doses received by workers at commercial LWRs during each of the years 1973 through 1984. This distribution is the sum of the annual dose distributions reported by each licensed LWR each year. As previously mentioned, the distribution reported by each LWR site for 1984 is shown in Appendix B. The table shows that the number of monitored individuals continues to increase while the collective dose appears to be leveling off. However, the values of CR* show that the percentage of the collective dose due to individual doses greater than 1.5 rems (cSv), has shown a general decrease from its 1973 value of 72% to about 55% in 1984. The distributions shown in Table 4.4 have been adjusted for the number of individuals that may have been reported by more than one site (see Section 5 for a discussion of the methodology). Appendix D provides unadjusted dose distributions for BWRs and PWRs separately for the years 1980 through 1984.

4.4 Average Annual Whole Body Doses

Some of the data presented in Tables 4.1, 4.2, and 4.3 are graphically displayed in Figure 4.1, where it can be seen that the average collective dose and average number of workers per BWR have been higher than those for PWRs since 1974 and that the values of both parameters, in general, continued to rise at both types of facilities until 1982. At that time, the average collective dose per reactor appeared to begin leveling off or decreasing slightly, as did the number of workers. However, in 1984 the average number of workers per reactor reached an all-time high at both BWRs and PWRs, which resulted in lower average doses at both types of facilities.

Figures 4.2 and 4.3 are plots of much of the information that is given in Tables 4.1, 4.2, and 4.3. The values of all of the parameters plotted, except the number of workers and electricity generated, decreased somewhat from last year's values. In looking at these figures and the fluctuations in the parameters for the years following the incident at the Three Mile Island Plant in 1979, one suspects that they reflect some of the impact that this incident had on the nuclear power industry.

To further assist in the identification of any trends that might exist, Figure 4.4 displays the average and median** values of the collective dose per reactor for BWRs and for PWRs for the years 1973 through 1984. The ranges of the values reported each year are shown by the vertical lines with a small bar at each end marking the two extreme values. The rectangles indicate the range of values of the collective dose exhibited by those plants ranked in the twenty-fifth through the seventy-fifth percentiles. Since the median values usually are not as greatly affected by the extreme values of the collective doses, they do not normally fluctuate as much from year to year as do the average values. The median collective dose for PWRs continues to range between 400 and 500

*See definition in Section 3.1.8.

**The value at which 50% of the reactors reported greater collective doses and the other 50% reported smaller collective doses.

Table 4.4

SUMMARY DISTRIBUTION OF
ANNUAL WHOLE BODY DOSES AT COMMERCIAL LIGHT WATER REACTORS
1973 - 1984

YEAR	Number of Individuals with Whole Body Doses in the Ranges (rems or cSv)																	Total Number Monitored	Number with Measurable Exposure	**Total Collective Dose (person-rems or person-cSv)	CR ***

*Summary of reports submitted in accordance with 10 CFR 20.407 by plants that had been in commerical operation for at least one full year as of December 31 of each of the indicated years. Figures shown for the years 1977 - 1984 have been adjusted for the multiple reporting of transient individuals (see Section 5).

**The collective dose and CR were not reported by the facilities but were calculated by the NRC staff using methods described in this document.

***CR is the ratio of the annual collecive dose delivered at individual doses exceeding 1.5 rems (cSv) to the total annual collective dose.

Figure 4.1

AVERAGE COLLECTIVE DOSE AND NUMBER OF WORKERS PER REACTOR 1973 - 1984

1973 - 1984

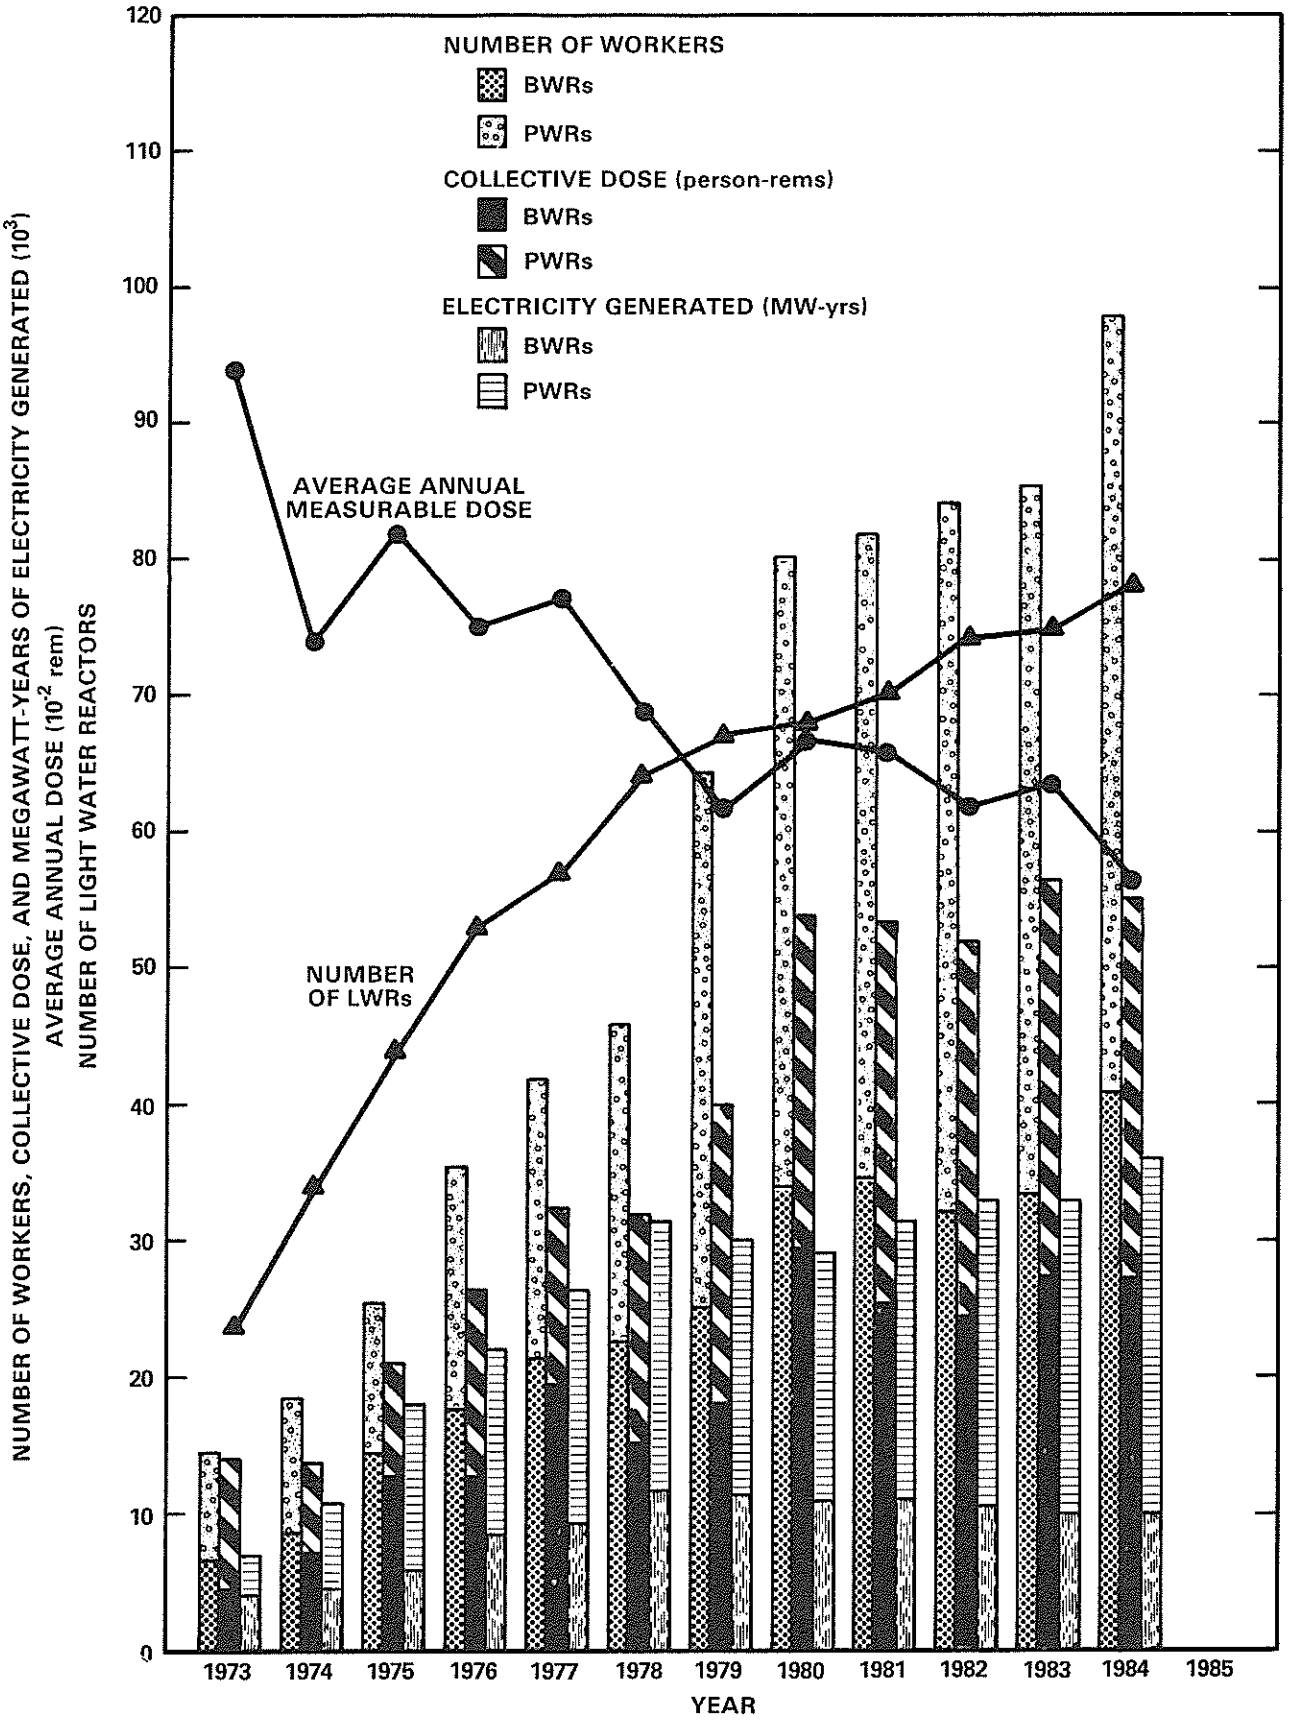

Figure 4.3
AVERAGE ANNUAL VALUES AT LWRs
1973 - 1984

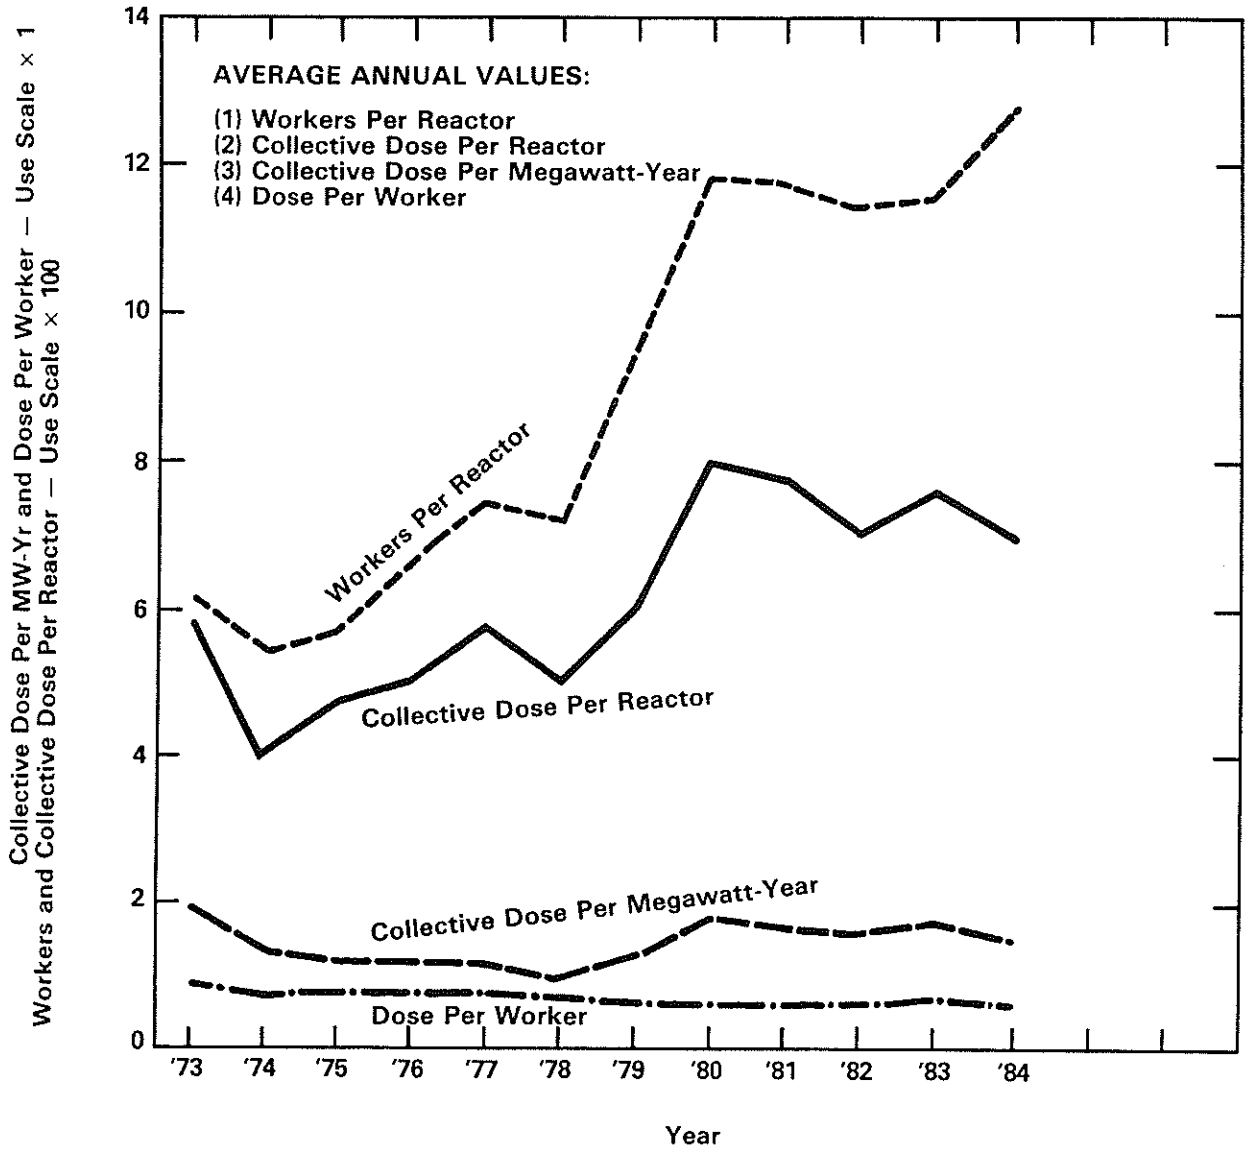

Figure 4.4

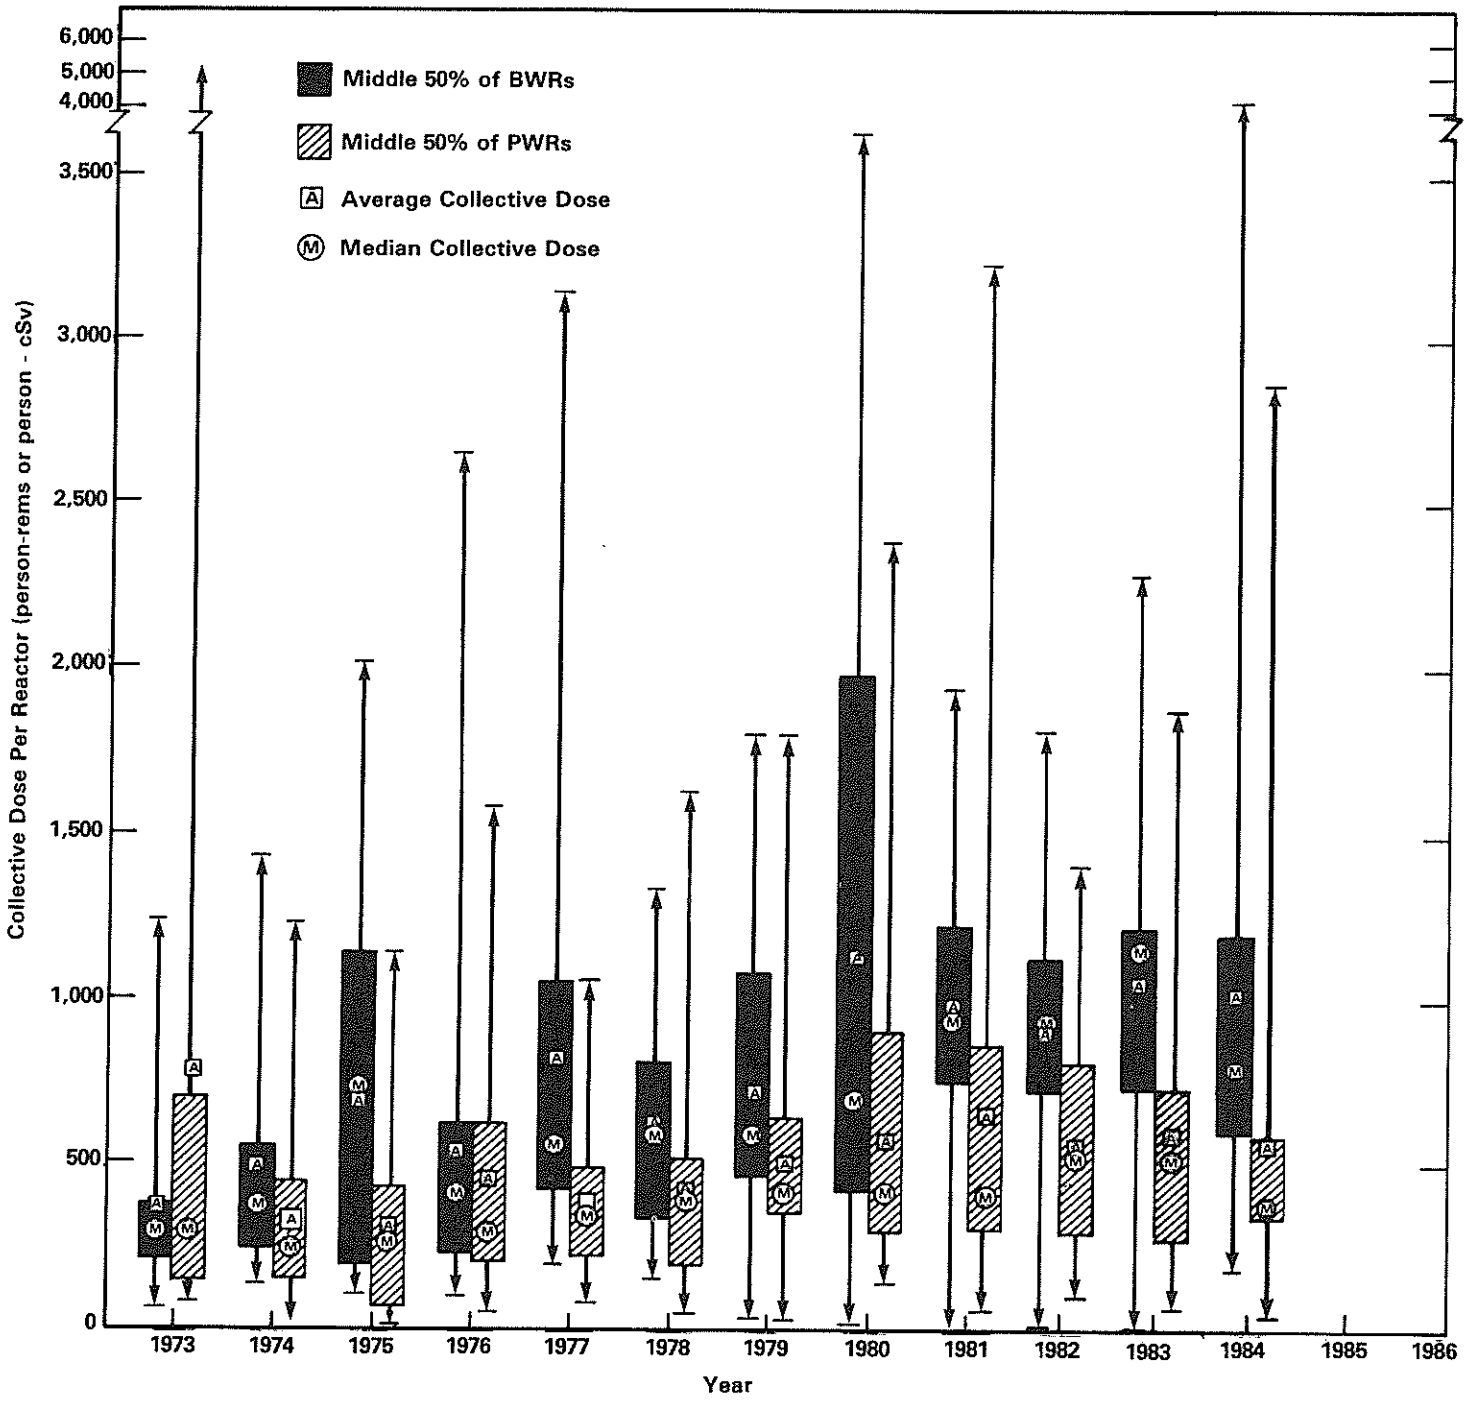
AVERAGE, MEDIAN AND EXTREME VALUES OF THE COLLECTIVE DOSE PER REACTOR 1973 - 1984



person-rems (person-cSv). At BWRs the median fluctuates more from year to year, and in 1984 the median decreased to 790 person-rems (person-cSv), which was still nearly twice that found for PWRs (395 person-rems (person-cSv)). Figure 4.4 also shows that in 1984 fifty percent of the PWRs reported collective doses between 340 and 570 person-rems (person-cSv) while fifty percent of the BWRs reported collective doses between 590 and 1,170 person-rems (person-cSv). Nearly every year, the median collective dose is less than the average, which indicates that the collective dose for most plants is less than the average collective dose per reactor (the value that is widely quoted).

4.5 Plant Rankings by Collective Dose per Reactor

The number of reactors from which data have been collected is still rather small, and the information reported by a few reactors where unusual conditions or problems may have occurred could have a large impact on some of the statistics presented in this report. In an effort to identify those plants, Tables 4.5 and 4.6 list the BWRs and PWRs in ascending order of person-rems (person-cSv) per reactor for each of the five years from 1980 through 1984. Two other parameters, dose per worker and collective dose per megawatt-year, are also given for each plant and could have been used in listing the plants as well. Also shown is a parameter "CR" which is defined to be the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems (cSv) to the total annual collective dose. In 1984 the value of CR for about 65% of the U.S. plants fell within the range 0.05 to 0.50 which is recommended by the UNSCEAR [Ref. 10]. Most of the reactors having values of CR greater than 0.50 were BWRs, the highest value being 0.87.

Table 4.7 lists the plants that had been in commercial operation for at least five years as of December 31, 1984, and shows the values of several parameters for each of the sites. It also gives a number of averages for the two types of reactors. Based on the 125 reactor-years of operation accumulated by the 25 BWR sites listed, the average annual collective dose per reactor was found to be 1,067 person-rems (person-cSv), the average measurable dose was 0.80 rems (cSv), and the average collective dose per megawatt-year was 2.7. Based on the 170 reactor-years of operation by the 34 PWR sites listed, these averages were found to be 569 person-rems (person-cSv), 0.59 rem and 1.3, respectively.

In 1984, there were five BWR units where collective doses that exceeded 1,500 person-rems (person-cSv) were accumulated. Although these five units represented only 18.5% of the 27 BWRs operating in 1984, they contributed nearly 44% of the total collective dose incurred at BWRs in 1984. Most of the collective dose accumulated at the BWR site with the highest collective dose (4,082 person-rems (person-cSv)) was attributed to the replacement of all the recirculation system piping.

At PWRs, there were five units where the collective dose exceeded 1,100 person-rem (person-cSv). Although representing less than 10% of the 51 PWRs operating in 1984, they contributed nearly 32% of the total collective dose at PWRs in 1984. The plant with the highest collective dose (2,880 person-rems (person-cSv)) in 1984 accumulated most of the dose during the replacement of steam generators.

[1]For sites with more than one operating reactor, the collective dose per reactor is obtained by dividing the collective dose for the site by the number of reactors.
[2]CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems (cSv) to the total collective dose.

[1]For sites with more than one operating reactor, the collective dose per reactor is obtained by dividing the collective dose for the site by the number of reactors.
[2]CR is the ratio of the annual collective dose delivered at individual doses exceeding 1.5 rems (cSv) to the total collective dose.

*For sites with more than one operating reactor, the collective dose per reactor is obtained by dividing the collective dose for the site by the number of reactors.

**Sites where not all reactors had completed five full years of commercial operation as of 12/31/84 are not included.

In general, particularly for BWRs, the plants having the lower values of most of the parameters shown are usually the newer plants. Some of the older, smaller plants also appear near the top of the listings since they report small collective doses; however, the ratio of their collective dose to the number of megawatt-years of electricity generated will be higher because of their limited power generation capacity. In the case of PWRs, this generalization does not always apply. For example, Prairie Island and Susquehanna, three reactors that have been operating for 10 or 11 years, have experienced lower collective doses than many newer reactors for years.

Usually, the combination of a large annual collective dose and a large collective dose to megawatt-year ratio for a plant indicates that extensive maintenance or modifications were undertaken during the year. For example, maintenance jobs that were large contributors to BWR doses in 1984 included replacement of recirculation system piping, inspection for intergranular stress corrosion cracking (IGSCC), IGSCC repair, Mark I torus modifications, and reactor vessel component inservice inspection. The PWR facilities reporting high values for these two parameters during the last few years generally have been involved in extensive tube inspection, sleeving, and plugging related to the repair of steam generators. It should be noted that the differences in nuclear plant designs and the ages of plants [Ref. 15], even between plants of a given type, affect the nature of these parameters as well, and one should be careful when attempting to draw conclusions from these data.

4.6 Collective Dose by Work Function and Employee Type

A second type of annual statistical report that is required by each plant's technical specifications provides the collective dose of workers monitored at each plant site by employee type (plant, utility, or contractor) and by work and job functions. The report submitted for each reactor site, after undergoing any necessary standardization, is provided in Appendix D. Summaries of the collective doses shown in these reports are given in Tables 4.8, 4.9, and 4.10. The collective doses obtained from these reports are not used in any other tables in this document for the following reasons: the technical specifications of each plant requires only 80% of the plant's collective dose be accounted for, and some plants do not use the official dosimeter results in compiling the data.

Table 4.8 provides a detailed summary of the distribution of collective dose by work function and personnel types for BWRs, PWRs, and all LWRs. It shows that contract workers performing special maintenance at LWRs continue to incur the largest portion (35%) of the collective dose. Table 4.9 presents a more general summary of these data for the last ten years, and one can see that the collective dose incurred during routine and special maintenance activities has ranged between 67% and 77% during these years. Figure 4.5 graphically shows the trends in the collective dose by work function and type of personnel for the years 1979 through 1984 for BWRs and PWRs separately. Contractor personnel incur most of the collective dose during special maintenance while it is nearly equally divided between contractor and plant and utility personnel during routine maintenance and waste processing and that the figures are fairly stable from year to year. Because of this stability and the fact that a number of these reports are not submitted in a standard format, summaries of these data will not be presented in future reports of these NUREG series.

* Table does not include results from the PWRs at Point Beach 1,2 (737 man-rems) because of formatting problems.

** These values are higher than usual because the dose incurred during various maintenance activities while Salem 1 was refueling was attributed to the refueling work function.

Figure 4.5

COLLECTIVE DOSE BY WORK FUNCTION AND PERSONNEL TYPE
AT BWRs and PWRs, 1979-1984

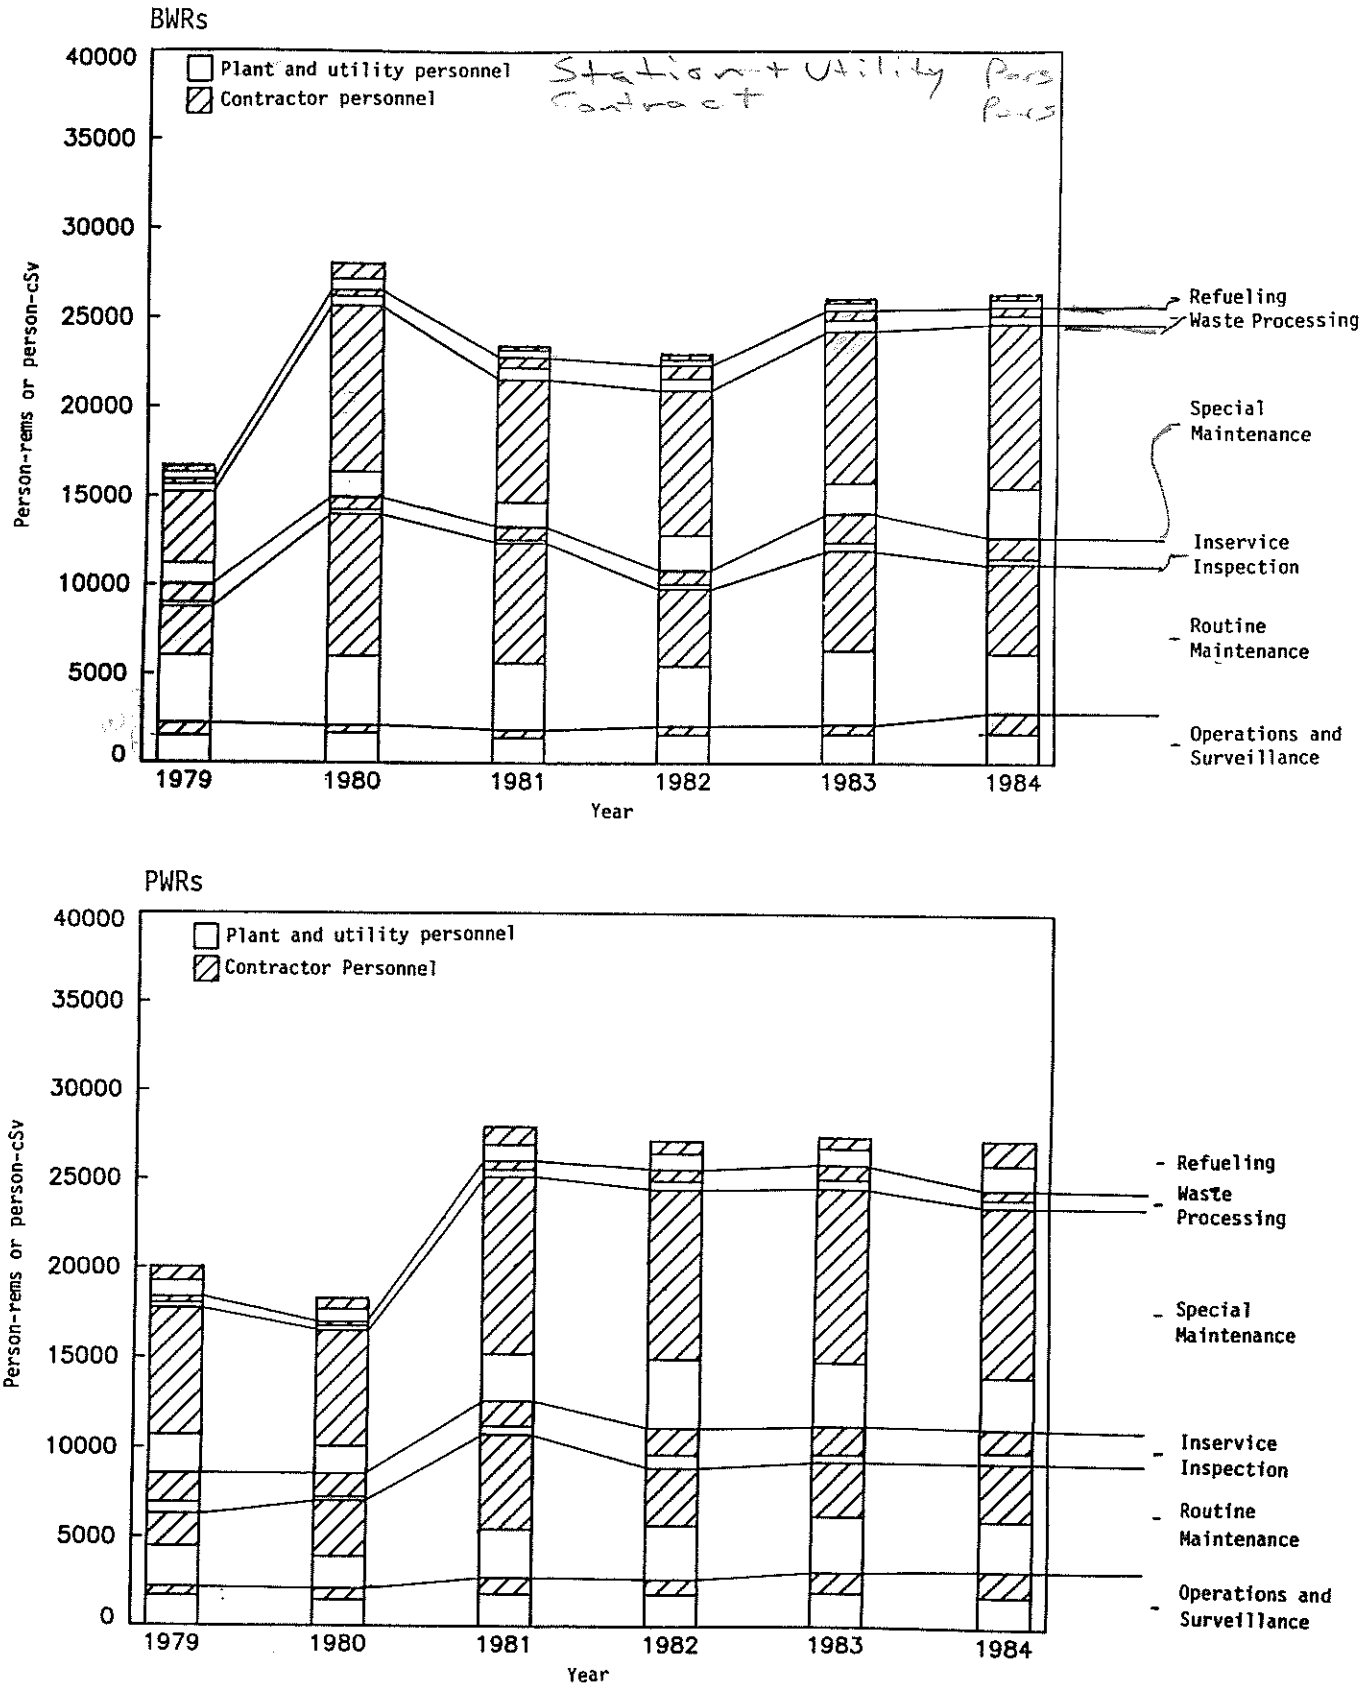

Table 4.10 presents the distribution of the collective dose for 1984 at all LWRs among five occupations. As expected, maintenance personnel incurred the majority (70.6%) of the collective dose with contractor maintenance personnel receiving about twice as much as the station and utility maintenance employees combined. This is about the same as that reported for 1983. Supervisory personnel received 4.1% of the dose, compared to 2.7% in 1983, while workers in the remaining three occupations--operations, health physics, and engineering--received 6.8%, 11.0%, and 7.5%, respectively, of the collective dose. None of these values changed very much from those found for 1982 either. The collective doses shown in Tables 4.8 and 4.10 do not equal those shown in other tables in the report because they are the sum of the doses taken from the type of annual reports shown in Appendix D rather than the collective dose that was obtained or calculated from the § 20.407 annual reports.

Another use made of the reports given in Appendix D is in proportioning the collective dose obtained from the § 20.407 annual reports into the work functions and personnel types shown in Appendix C. This was done in the following way:

(1) The collective dose incurred by workers in the work function "Reactor Operations and Surveillance" on each plant's annual report submitted pursuant to their technical specifications (the first number in the last column in Appendix D) was determined.

(2) The ratio of this dose to the total collective dose (the last number in the last column in Appendix D) was calculated and multiplied by the total collective dose that had been estimated or obtained from the § 20.407 annual report. This product is the collective dose shown in the column headed "Operations" in Appendix C.

(3) The collective dose shown in the column headed "Maintenance and Others" in Appendix C was determined by first summing the collective doses incurred by workers in the five remaining functions given in Appendix D and then calculating the fraction that this dose is of the total collective dose. This fraction was multiplied by the total collective dose estimated from the § 20.407 annual reports to yield the collective dose shown in this column of Appendix C.

(4) A similar procedure was followed in determining the collective dose for the columns headed "Contractor" and "Station & Utility" in Appendix C.

4.7 Health Implications of Average Annual Doses

If any damage to health is caused by exposure to radiation in the workplace, it would likely manifest itself as certain types of cancer in the exposed worker or, less likely, as inherited genetic damage in the first few generations of the workers' offspring. However, the likelihood of cancer or genetic damage occurring as a result of radiation exposure experienced by workers in the nuclear industry is small. A vast amount of scientific information is available from which estimates of these risks can be made. Much of this information, however, has been obtained from epidemiologic studies of human populations at levels of exposure considerably higher than those normally experienced in the workplace. Complementary to this, information obtained from many animal and cell biology

studies have greatly enhanced our knowledge and understanding of the biological effects of ionizing radiation. Although using this information to estimate risks in the workplace introduces uncertainties, these uncertainties can be dealt with in such a manner that the risk is not likely to be underestimated. Thus, the discussion below is likely to overstate the health implications rather than understate them.

Cancer induction as a result of radiation exposure has been examined by many organizations having scientific and medical expertise in the subject. One of these, the National Academy of Sciences (NAS), published a comprehensive review of the biological effects of ionizing radiation in 1980 [Ref. 16]. Based on this report, a large working population receiving one million person-rems (person-cSv) might suffer an estimated 100 to 200 additional cancer deaths over the remaining years of their lives. This risk estimate can be applied to the 59,400 person-rems (person-cSv) (Table 3.1) and the 108,500 workers who received measurable exposures in 1984. The result is that for these workers the expected number of additional cancer deaths that might result from radiation dose received that year would be about twelve.* These deaths would occur many years following the exposure and would be in addition to the approximately 20,000 cancer deaths that occur normally in a population of 108,500 workers without exposure to this amount of radiation. Perhaps more meaningful to the individual workers are the health implications to the workers receiving the average dose of 0.55 rem (cSv) or the maximum dose of eight or nine rems (cSv) during 1984. The estimated increased cancer death risk is about one chance in 10,000 for the average dose and about one chance in 1,000 for the maximum dose. Should a worker receive 0.55 rem (cSv) per year continuously during his entire working career (working from age 20 until age 65) his risk of dying from cancer could increase by less than 2% over the normal risk of dying of cancer. These risks can be compared to the American Cancer Society's estimates of one chance in four of developing cancer and one chance in five of dying of cancer.

The potential genetic effects from a worker population receiving about 59,400 person-rems (person-cSv) is very small compared to genetic damages that normally occur spontaneously in a population of this size. Approximately 100,000 serious genetic defects occur normally in one million live births, i.e., an average of about one serious defect in every ten live births. Theoretically, the total genetic damage in the first generation children of the 108,500 exposed* workers would, according to the 1980 NAS report, be an increase of four or less cases (less than 0.05%)* compared to the expected 10,000 cases that occur normally. No significant increase in the number of genetic defects has been observed in the children of individuals exposed to ionizing radiation at Hiroshima and Nagasaki, Japan.

*Assuming that, on the average, each exposed person will have one child in the future, i.e., 108,500 children born to this worker population.

5 TERMINATION DATA SUBMITTED PURSUANT TO 10 CFR § 20.408

5.1 Termination Reports, 1969-1984

In 1969, the Atomic Energy Commission (predecessor of the NRC) began requiring certain categories of licensees* to submit personal identification and exposure information upon the termination of each monitored person's employment or work assignment in the licensee's facility. The appropriate information on each report has been manually coded and entered into the Commission's computerized Radiation Exposure Information Reporting System (REIRS) for permanent retention. The data are retrievable by several criteria - social security number, name, facility, etc. - which allows statistical analysis of the data as well as the tracing of individual dose histories. During the years that this information has been collected, some 1,500,000 termination records have been received for approximately 350,000 individuals who have been reported as having terminated their employment at facilities in one or more of the categories of covered licensees. The figures given for the number of reports and the number of individuals are different because numerous individuals have been terminated more than once over the years and because some individuals may have had external doses reported for more than one part of the body, as well as estimates of internal depositions of radioactive material, each of which is counted as one record. Table 5.1 provides a breakdown of this information for individuals terminating during each of 16 years and, since the majority of termination reports are now submitted by nuclear power facilities, the number of records and individuals that they reported are displayed separately. One can see that the number of records continues to increase each year, primarily because of the growing need for workers at power reactors.

5.2 Limitations of Termination Data

When examining or using the statistics that are based on the termination data, one should keep in mind that these data have various limitations: (1) some licensees submit a termination report for each monitored contractor employee at the end of each monitoring period rather than waiting until the individual actually completes his work assignment at the facility, (2) the period(s) of exposure that are reported for terminating individuals may indicate the monitoring period during which he may have been exposed to radiation rather than the actual dates of exposure, (3) some licensees report cumulative periods of exposure and doses rather than the actual periods and dose incurred during each period, and (4) licensees having more than one licensed facility sometimes include in the termination report submitted when the individual leaves the second facility the dose that he incurred at the first facility, which may already have been reported. Although attempts have been made to correct for some of these problems, they are still a small additional source of error in any statistics developed from the termination data.

---

*Commercial nuclear power reactors; industrial radiographers; fuel processors, fabricators, and reprocessors; and manufacturers and distributors of specified quantities of byproduct material. Three other types of NRC licensees are now required to submit reports pursuant to 10 CFR §§ 20.407 and 20.408: geologic repositories for high-level radioactive waste; receivers of radioactive waste from other persons for land disposal; and independent installations for the storage of spent fuel.

Table 5.1

*Commercial nuclear power reactors; industrial radiographers; fuel processors, fabricators, and reprocessors; manufacturers and distributors of specified quantities of byproduct materials; low-level waste disposal facilities; independent spent fuel storage installations; and geologic high-level waste repositories.

**The termination data for about 15% of the individuals terminating during 1983 or 1984 have not been entered into the REIR System.

5.3 Transient Workers per Calendar Quarter

One use of the information contained in the termination reports is the examination of the doses being received by short-term workers. Since nearly half of the termination reports indicated periods of exposure that were less than 90 days, it is possible that several thousand individuals could have been employed by two or more licensees during the same calendar quarter. Thus, in this report, a "quarterly transient" worker is defined to be an individual who began and terminated employment at two or more different licensed facilities within one calendar quarter. This allows one to examine the doses of those workers most likely to approach the quarterly limits without their employer's knowledge since they move so rapidly among facilities.

Table 5.2 displays some of the information gathered from these termination reports that were submitted by all covered licensees and by licensed nuclear power facilities, separately. One can quickly see that the vast majority of these individuals are monitored by nuclear power facilities. The number of these individuals increased about twentyfold during the five years 1972 through 1976, but has remained between 2,350 and 2,550 since 1981. The top part of Table 5.2 also shows that the average individual dose (which is close to being a quarterly dose for these workers) continues to decrease, dropping to an average dose of 0.26 rem (cSv) in 1984.

The bottom half of the table separates the information shown for power reactor licensees into that for reactor workers employed by two, three, and four or more different reactor licensees. The table shows that most of these transients were reported by two different licensees during a quarter. The smaller number of workers terminated by three or more licensees received higher average doses than those terminated by two employers every year until 1982. From that year onward, the average dose of workers terminated from three or more facilities has been about the same or less than the average dose of the workers terminating from two nuclear power licensees.

Examination of these records also revealed that some individuals have worked for as many as six different NRC licensees during one calendar quarter. However, on the average, less than two instances per year have been found in which a worker exceeded his quarterly limit of three rems (cSv) as a result of his working at two or more different licensed facilities within one calendar quarter. In a few of these instances, the doses that the workers had received while employed by the first utility were revised upward later in the year. The underestimates resulted in quarterly doses that slightly exceeded three rems (cSv). A very few quarterly exposures exceeding three rems (cSv) may have gone undetected because a worker's dose was received over a period spanning a calendar quarter and was reported for the entire period. When this happens, it is not possible to determine the portion of the dose received during each quarter.

5.4 Transient Workers per Calendar Year

Since the number of transient workers per calendar quarter comprise only a small percentage of the total number of individuals terminating each year, it was decided to change the criteria so that the records of more workers would be examined. This was done by selecting the records of all individuals who began and terminated two or more periods of employment with at least two different reactor facilities within one calendar year and summing each worker's whole body doses. An examination of these data would allow one to determine the number and average dose for these "annual transients." Since more than 95% of these transients are reported by nuclear power facilities, only the termination records of these individuals were examined in detail. Table 5.3 summarizes the number and doses of the transients found among the individuals terminating during the eight years from 1977 through 1984. The number of these workers increased from about 3,200 workers in 1977 to about 6,000 in 1984. However, after reaching a high of about 6,000 person-rems (person-cSv) in 1980, the collective dose incurred by these workers decreased to about 5,500 person-rems (person-cSv) in 1984. The average dose also decreased somewhat in 1984 to a value of 0.91 rem (cSv).

1984*	4,219	3,350	0.81	1,066	1,236	1.16	739	856	1.16

*Figures for these years may be incomplete because the termination data for about 15% of the individuals terminating during 1983 or 1984 have not been entered into the REIR system.

The lower portion of Table 5.3 shows the number and doses of workers who were terminated by two, three, and four or more different licensees during each calendar year. In 1984 there were sharp decreases in the collective and average doses of workers terminated by more than two facilities. This is probably due to the utilities' increased efforts to keep the annual doses of all workers less than five rems (cSv). This is further borne out by the fact that, as shown in Table 5.4a, the distribution of the doses of these transient workers was such that there were only 11 workers with doses greater than five rems (cSv) in 1984. Table 5.4a shows that in prior years, there were usually between 50 and 100 transient workers with annual doses greater than five rems (cSv).

Another way in which the distribution of the doses received by transient workers can be useful is in the determination of the impact that the inclusion of these individuals in each of two or more licensee's annual reports had on the annual summary (Table 4.4) for all nuclear power facilities (one of the problems mentioned in Section 2). Table 5.4a shows the actual distribution of these transient workers' doses as determined from the above-described termination reports and compares it with the distribution of the doses of these workers as they would have appeared in a compilation of the annual statistical reports submitted by each of the nuclear power facilities. During each of the years shown, each of the transient workers was counted an average of 2.6 times. This was not surprising because some individuals were reported by as many as nine different facilities.

Table 5.4b illustrates the impact that the multiple reporting of these transient workers had on the staff's compilations of the annual statistical reports for the years 1978 through 1984. Since each nuclear power facility reports the distribution of the doses received by workers while monitored by the particular facility during the year, one would expect that a summation of these reports would result in individuals being counted several times in dose ranges lower than the range in which their total accumulated dose (the sum of the personnel monitoring results incurred at each facility during the year) would actually place them. Thus, while the total collective dose would remain the same, the number of workers, their dose distribution, and average dose would be affected by this multiple reporting. This was found to be true because too few workers were reported in the higher dose ranges. For example, in 1983 the compiled annual reports indicated that 85,694 workers received a measurable dose, 85 of whom received doses greater than five rems (cSv). After accounting for those individuals that were reported more than once, the adjusted distribution indicated that there were only 80,552 workers that received a measurable dose and that 163 of them received doses greater than five rems (cSv). This resulted in an average measurable dose of 0.70 rem (cSv) rather than the 0.66 rem (cSv) obtained from the compiled reports.

Since the number of transient workers receiving measurable doses is only about 5% of the total number of workers receiving measurable doses during the year, their impact on most of the statistics derived from compilations of the annual summary reports is not very great. However, when examining the number of annual doses exceeding five rems, one finds that the adjusted statistical distribution indicates that the number of workers who received doses greater than five rems (cSv) was between 50 and 80 more than the number found in the compiled statistical distribution each year until 1984. This is more clearly shown in Table 5.5, where it can also be seen that in 1984 the number of workers receiving doses greater than five rems (cSv) was found to be 11 workers. Most of this reduction

Table 5.4 a

[c]Distribution found by subtracting the actual from the compiled distribution shown inTable 5.4a and then subtracting this difference from the compiled statistical distribution shown in Table 5.4b.

is probably due to the fact, as stated in the footnote, that not all of the 1984 termination reports had yet been processed. After discussions with several firms that provided contract personnel to work at nuclear power facilities during 1984, it was determined that 110 would be a more realistic estimate of the number of workers with annual doses greater than five rems.

Table 5.5

ANNUAL WHOLE BODY DOSES EXCEEDING FIVE REMS (cSv)

Year	Compiled Number >5 Rems (cSv)	Adjusted Number >5 Rems (cSv)	Percent of Workers
1977	270	351	0.9
1978	103	158	0.4
1979	130	180	0.3
1980	311	391	0.5
1981	189	235	0.3
1982	74	135	0.2
1983*	85	163	0.2
1984*	0	11(110)**	<0.1(0.1)**

*Figures for these years may be incomplete because the termination data for about 15% of the individuals terminating during 1983 or 1984 have not been entered into the REIR system.

**Estimate based on discussions with firms providing contract personnel.

5.5 Temporary Workers per Calendar Year

To complete the exmination of the doses received by the short-term workers employed at nuclear power facilities, Table 5.6 summarizes the data compiled on "temporary workers". For purposes of this report, temporary workers were defined to be those individuals who began and ended their employment at only one nuclear power facility during the calendar year. Table 5.6 shows that the number of these temporary individuals has increased by some 64% between 1977 and 1984 while the number of reactors has increased by about 40% during this time. The number of temporary workers receiving a measurable dose, however, has increased by only 27%. The average dose per monitored individual remains at about 0.30 rem (cSv) and, since about half of them received less than measurable doses, the average measurable dose remains at about 0.60 rem (cSv). Comparison of these figures with those in Table 5.4b reveals that these workers comprised 28% of the total number of workers (92,918) receiving a measurable dose in 1984, while their collective dose was only 26% of the total collective dose. Their average measurable dose was also slightly less than the overall average of 0.59 rem (cSv).

Table 5.6

TEMPORARY WORKERS PER CALENDAR YEAR
(Individuals Terminated by Only One Employer)

Year	No. of Reactors	Number of Temps. Monitored	Number with Measurable Doses	Collective Dose (person-rems or person-cSv)	Average Dose (rem or cSv)	Average Measurable Dose (rem or cSV)
1977	57	29,090	19,094	11,373	0.39	0.60
1978	64	28,864	17,110	9,821	0.34	0.57
1979	68	38,347	21,491	9,488	0.25	0.44
1980	69	48,383	28,305	16,168	0.33	0.57
1981	71	48,265	28,675	16,755	0.35	0.58
1982	75	44,503	25,646	14,266	0.32	0.56
1983*	76	47,428	24,144	14,902	0.31	0.62
1984*	79	47,622	26,188	14,653	0.31	0.56

*Figures for these years may be incomplete because the termination data for about 15% of the individuals terminating during 1983 or 1984 have not been entered into the REIR System.

5.6 Dose Distribution by Sex

In 1980 the sex of terminating individuals was first entered into the REIR System, along with the usual identification and dose data that have always been entered. Since the sex of the individual is not normally indicated on the termination reports, the sex was determined by examining the first name or salutation of each individual for whom either one was shown. The REIR System now contains the sex of about 65% of the individuals terminating since 1980.

Table 5.7 summarizes the results of several analyses of the termination data submitted for individuals for whom the sex had been entered in the REIR System. Females comprise between 5% and 8% of the total number of the annual transients (individuals beginning and ending one or more periods of employment during the year). Table 5.7 also shows that the collective dose incurred by these females is only about 1.3% of the total collective dose incurred by the total number of annual transients. Consequently, the average measurable dose for female workers was found to be 0.26 rem (cSv) while it was 0.73 rem (cSv) for the male workers terminating in 1983. Figure 5.1 shows the distribution of doses of these workers, and one can quickly see that some 90% of the females received doses that were less than 0.10 rem (cSv); only 65% of the males received such doses. There were no females in this population that received a dose greater than five rems (cSv), but there were about 100 male workers that received doses between five and nine rems (cSv) in 1983, the last year for which this analysis was done.

Table 5.7

SEX VS DOSE PROFILES OF TERMINATED INDIVIDUALS

	1980 Females	1980 Males	1981 Females	1981 Males	1982 Females	1982 Males	1983 Females	1983 Males

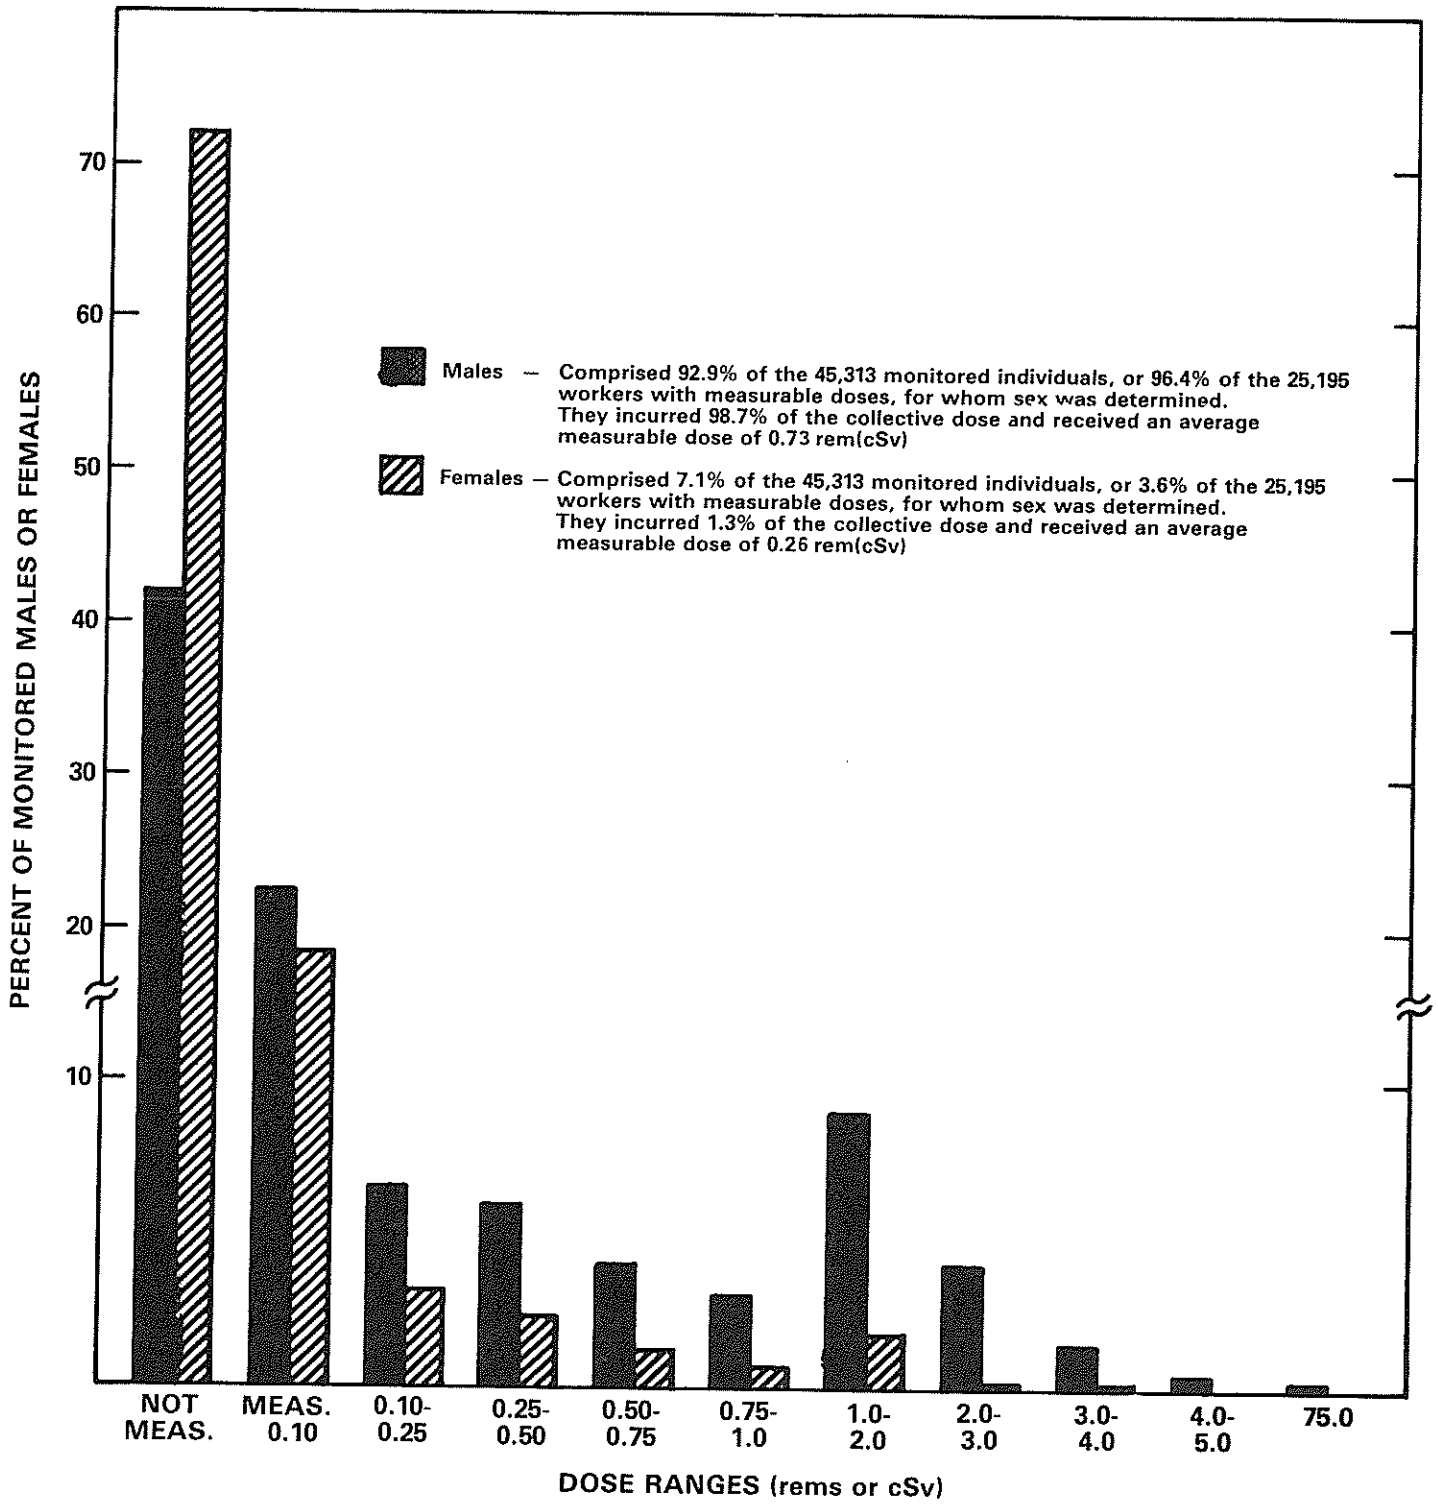
Figure 5.1
Dose Distribution of Males and Females Terminating from LWRs
1983



5.7 Age Distribution

Since the REIR System contains birth dates for about 60% of the approximately 300,000 individuals that have terminated from nuclear power facilities since 1969, it is possible to examine the age distribution of these terminated workers. Table 5.8 shows the percentage of these individuals in each of twelve age groups, ranging from 20 years old to 79 years old as of the year 1985. There is a small portion of the workers less than 25 or older than 65 with the vast majority (63.8%) being between 25 and 45 years of age.

Table 5.8

AGE DISTRIBUTION OF TERMINATED REACTOR WORKERS
AS OF 1985

Age Range (Years)	Percent in Range
20-24	2.0
25-29	12.4
30-34	18.1
35-39	19.1
40-44	14.1

6 PERSONNEL OVEREXPOSURES - 10 CFR § 20.403 and 10 CFR § 20.405

6.1 Control Levels

One requirement of the above-referenced sections of Part 20, Title 10, Chapter I, Code of Federal Regulations, is that all persons licensed by the NRC must submit reports of all occurrences involving personnel radiation exposures that exceed certain control levels, thus providing for investigations and corrective actions as necessary. The term "overexposure" is not necessarily intended to indicate that a worker has been subjected to an unacceptable biological risk. Based on the magnitude of the exposure, the occurrence may be placed into one of three categories:

(1) Category A

10 CFR § 20.403(1) - Exposure of the whole body of any individual to 25 rems (cSv) or more; exposure to the skin of the whole body of any individual to 150 rems (cSv) or more; or exposure of the extremities (feet, ankles, hands or forearms) of any individual to 375 rems (cSv) or more. The Commission must be notified immediately of these events.

(2) Category B

10 CFR § 20.403(b) - Exposure of the whole body of any individual to 5 rems (cSv) or more; exposure of the skin of the whole body of any individual to 30 rems (cSv) or more; or exposure of the extremities to 75 rems (cSv) or more. The Commission must be notified within 24 hours of these events.

(3) Category C

10 CFR § 20.405 - Exposure of an individual to radiation or concentrations of radioactive material that exceeds any applicable quarterly limit in Part 20 or in the licensee's license but is less than the values given above. This includes reports of whole body exposures that exceed 1.25 rems (cSv), or that exceed 3 rems (cSv), as discussed in Section 3.2. Reports of skin exposures that exceed 7.5 rems (cSv) and extremity exposures that exceed 18.75 rems (cSv) are included, and reports of exposures of individuals to concentrations in excess of the levels given in 10 CFR § 20.103 and Appendix B usually fall into this category as well. These reports must be submitted to the Commission within 30 days of the occurrence.

6.2 Summary of Overexposures

Table 6.1 summarizes all the occupational overexposures to external sources of radiation as reported by Commission licensees pursuant to § 20.403 and § 20.405 during the years 1977 through 1984. For 1982, 1983, and 1984, it shows the number of individuals that exceeded various limits while employed by one of several types of licensees. For the years 1977 through 1981, only the overexposures reported by licensed industrial radiography firms are shown separately. Most of the occurrences included in the "Others" category come from research

[a]This person simultaneously received an extremity overexposure of 61 rems (cSv) that is not shown.
[b]This person simultaneously received a skin overexposure of 15.2 rems (cSv) that is not shown.
[c]One of these persons simultaneously received an extremity overexposure of 21 rems (cSv) that is not shown.
[d]One of these persons simultaneously received an extremity overexposure of 46 rems (cSv) that is not shown.
[e]One of these persons simultaneously received an extremity overexposure of 45 rems (cSv) that is not shown.
[f]These two persons simultaneously received extremity overexposures of 82 and 38 rems (cSv) that are not shown.
[g]This person simultaneously received a skin overexposure of 13 rems (cSv) that is not shown.
[h]This person simultaneously received an extremity overexposure of 18 rems (cSv) that is not shown.
[i]This person simultaneously received an extremity overexposure of 26.9 rems (cSv) that is not shown.

facilities, universities, and measuring and well-logging activities. In 1980 the total number of individuals reported as being overexposed was 96, a considerable increase over the numbers reported for other years. This increase was due to the overexposure of some 67 individuals at one nuclear power facility during steam generator repair work. They received doses between three and five rems. In 1984, the total number of overexposed individuals was 19, which is the lowest number reported during the years shown. The highest whole body dose in 1984 was 8.2 rems (cSv). In each of the years from 1977 through 1983, the highest whole body doses were 220, 27.3, 17.0, 7.7, 9.4, and 25 rems (cSv), respectively.

There were two incidents in 1984 in which external exposures of the magnitude described in Category A or B were received. In one incident, a radiographer received a whole body dose of 8.2 rems (cSv) while performing radiography in a field site in Utah. The radiographer failed to perform adequate radiation surveys after making radiographic exposures and did not realize that the radiographic source had not returned to the fully retracted and shielded position.

In the second incident, the dosimeter worn by a nuclear medicine student indicated a whole body dose of 5.2 rems (cSv) for the month of December. Investigation failed to find the cause of exposure, and it was assumed that the student incurred the dose. Although both of these doses are all in excess of NRC limits, they are below the level where observable medical effects would be expected.

There were no instances in 1984 in which the estimated intake of radioactive material exceeded the quarterly intake limit, equivalent to exposure for 520 hours at the maximum permissible concentrations (MPC-hours). Both incidents involved thyroid uptakes of iodine-125 in which one individual received an estimated thyroid dose of 2,000 rems (cSv) or less and the other received a thyroid dose of 300 rems (cSv) or less. Both individuals were involved in research activities, and their excessive thyroid burdens were discovered during routine bioassays. It is doubtful that either was the result of excessive airborne concentrations of iodine-125, but exactly how the uptakes actually occurred was never discovered. No change in thyroid function was observed in either individual.

There was one report of personnel exposure to airborne concentrations of soluble uranium in excess of the applicable limit equivalent to exposure for 40 hours at the maximum permissible concentration in 1984. The report indicated that an uptake equal to 90 MPC-hours may have been incurred by an employee while working in a ventilation dust collection unit.

[a]Humboldt Bay has been shutdown since 1976 and in 1984, it was decided that it would not be placed in operation again. Therefore, it is no longer included in the count of commercial reactors.

*Indian Point 1 was defueled in 1975 and in 1984, it was decided that it would not be put in operation again. Therefore, it is no longer included in the count of commercial reactors.

**Indian Point 3 was purchased by a different utility and now reports separately.

*INDIAN POINT 1 was defueled in 1975 and in 1984 it was decided that it would not be placed in operation again. Therefore, it is no longer included in the count of commercial reactors.

**INDIAN POINT 3 was purchased by a different utility and now reports separately.

13. ABSTRACT (200 words or less)

This report summarizes the occupational radiation exposure information that has been reported to the NRC's Radiation Exposure Information Reporting System (REIRS) by nuclear power facilities and certain other categories of NRC licensees during the years1969 through 1984. The bulk of the data presented in the report was obtained from annual radiation exposure reports submitted in accordance with the requirements of 10 CFR 20.407. Data on workers terminating their employment at certain NRC licensed facilities were obtained from reports submitted pursuant to 10 CFR 20.408. The 1984 annual reports submitted by about 500 licensees indicated that approximately 195,000 individuals were monitoried, 171,000 of whom were monitored by nuclear power facilities. They incurred an average individual dose of 0.30 rem (cSv) and an average measureable dose of 0.55 rem (cSv). Termination radiation exposure reports were analyzed to reveal that about 67,500 individuals completed their employment with one or more of the 500 covered licensees during 1984*. Some 66,100 of these individuals terminated from power reactor facilties, and about 5,500 of them were considered to be transient workers who received an average dose of 0.91 rem (cSv).

*These figures may be incomplete because data for about 15% of the individuals terminating during 1984 has not been entered into REIRS.

14 DOCUMENT ANALYSIS - a. KEYWORDS/DESCRIPTORS
occupational radiation exposure
industrial radiography
power reactors
collective dose
average dose
transient workers
fuel fabricators
